ABSTRACT
News coverage of hazards is often commented to be of critical importance to individuals' perceived risk associated with tourist destinations. Despite the significance of this issue to the global tourism industry, the link between portrayals of hazards and audience reception is rarely studied in this context. This study adopted the framing theory to evaluate media effect on tourists' perceived risk of portrayals of terrorism and political instability incidents. This involved a survey-embedded experiment which manipulated potential elements of a news report concerning a hazard. The content of fictitious articles used in the experiment was created on the basis of extant risk perception theories. Results revealed that the use of risk amplifying frame and risk attenuating frame result in higher and lower ratings of risk respectively. Moreover, tourist psychographic characteristics were found to moderate the influence of news frames on perceived risk. Implications for tourism destination managers and marketers were discussed.

1. Introduction
The media coverage of hazards is fundamental as to the way in which some hazards are perceived as risky and some are trivialised (Flynn, Slovic, & Kunreuther, 2001; Kasterson, 2005; Petts, Horlick-Jones, & Murdock, 2001). Lack of personal experience with hazards such as terrorism or political instability (hereafter 'PI') increases audiences' reliance on secondary sources of information. Among these, the news media are often commented to be a particularly important source of risk perceptions of hazards and the tourist destinations in which they take place. While providing people with crucial information in a timely manner, news media coverage of hazards is commonly believed to be associated with producing distorted understanding of safety levels at destinations (Chew & Jahari, 2014; Larsen, Brun, Torvald, & Selstad, 2011; L’Etang, Falkheimer, & Lugo, 2007). Consequently, this is of importance to Destination Management Organisations (DMOs) who wish to minimise negative impacts of such coverage by understanding how potential tourists make sense and act upon this information and devising their own communication strategies to convey a more balanced view of the situation (Baxter & Bowen, 2004; Ritchie, Dorrell, Miller, & Miller, 2004).

Media scholars note that key to understanding the potential media effect on perception of risk is the way in which hazardous events are framed (Hove, Paek, Y., & Jwa, 2015; Hughes, Kitzinger, & Murdock, 2006; Marks, Kalaitzandonakes, Wilkins, & Zakhara, 2007). A number of studies demonstrate cases of mass media coverage of hazards which puts emphasis on some aspects of hazards to the exclusion of others (Daye, 2014; Spencer & Triche, 1994; Woods, 2007). It is widely agreed that the aspects of an issue highlighted by the speaker can influence the way audiences understand and interpret the issues covered (Price & Tewksbury, 1997). Tourism and hospitality studies that employ framing theory demonstrate that message frames can influence hotel booking intentions and trust (Sparks & Browning, 2011) and destination attractiveness (Min, Martin, & Jung, 2013). However, despite the
agreement among tourism scholars that news framing can cause destinations to appear safer or more dangerous (Hall, 2002), there is a paucity of empirical studies on tourists' responses to different portrayals of risk (risk frames). The need for a study in this area is reinforced by a recent call on framing effects research in tourism by Liu and Pennington-Gray (2015).

Beyond considering the influence of different ways of portraying hazards, framing effects scholars note that it is equally important to consider characteristics of the audiences (Lecheler, de Vreese, & Slothuus, 2009). This is especially relevant in the context of perceived risk, which is subjective and depends upon a broad range of tourist characteristics. Among these, the degree of allocentricity has seldom been used to understand variance in perceived risk. Plog (1974) model of allocentricity identifies tourists' personality along a continuum from allocentrics to psychocentrics. The allocentric type is described by Plog (2001; 2002) as more outgoing, adventurous and exploring, and self-confident than the psychocentric traveller.

Guided by framing effects theory and existing knowledge of perceived risk in tourism, this study sought to understand whether different media frames concerning hazards influence tourists' judgment of risk. Specifically, this study employed an experimental design to explore the impact of different portrayals of terrorism and PI hazards. Moreover, tourist characteristics of age, gender, and degree of allocentricity were considered as potential moderators of the media effect. The findings should provide needed empirical support for the often implied yet rarely tested influence of media messages on tourists' perception of risk. This issue is of significance from a theoretical standpoint and for the practice of communication strategies that help to recover problematic destination images.

2. Literature review

2.1. Risk perception

The concept of perceived risk, or subjective risk, in social scientific literature is commonly agreed to mean ‘the processing of physical signals and/or information about potentially harmful events or activities, and the formation of a judgement about seriousness, likelihood and acceptability of the respective event or activity’ (Slovic, Fischhoff, & Lichtenstein, 1982 cited by Grobe et al. 2008, p. 16; Brehmer, 1987; Renn, 2004). Proponents of the psychometric paradigm of risk (Fischhoff, Slovic, Lichtenstein, Read, & Combs, 1978) demonstrate that when evaluating risks, people are influenced by a host of qualitative risk features (see Table 1), or simplifying heuristics, which produce subjective biases and misjudgements of formal (quantitative) risk assessments (Fischhoff et al., 1978; Slovic et al., 1982). For example, the public is more concerned about involuntary risks (Slovic, 1987) and risk in affect-rich contexts such as terrorist attacks, than about less spectacular but much more probable ones such as heart disease (Lowenstein, Hsee, Weber, & Welch, 2001; Sjöberg, 2007).

2.2. Risk perception in tourism: terrorism and political instability

In tourism, risk perception is a function of uncertainty and consequences (Moutinho, 2000), with some consequences being more desirable to tourists than others. Although risk may entail positive and negative outcomes, it is often studied as undesirable outcomes, such as loss of time or money, that may arise from consuming tourism products, for example, trekking in unfamiliar environments. Risks identified include threats to health (e.g. food poisoning), and terrorism or PI, e.g. in hazards such as coups, kidnappings, bombings, and street disturbances. Terrorism and PI are often commented to be particularly intimidating risks due to the uncontrollable, involuntary and random nature of the potential harm involved in visiting destinations struck by such incidents (Cavlek, 2002; Heng, 2006). This is supported by Gray and Wilson (2009) who find that political hazards such as terrorism are perceived as riskier than other physical threats (e.g. weather) and social hazards (e.g. hostile local people). This may be partly attributed to the emotional charge carried by such events, which is further amplified by the man-made nature of harm involved, as opposed to acts of nature. One of the main consequences of man-made disasters is that, apart from the physical damage, the biggest impact is often felt on the psychological level (Jenkin, 2006; Schmid, 2005).

While related, PI and terrorism have a separate conceptual identity, which is supported by a number of authors who examine the phenomena from this perspective (e.g. Enders & Sandler, 1998; Richter & Waugh, 1986; Saha & Yap, 2013; Sonmez, 1998). Numerous and diverse definitions have been proposed over the years. In an attempt to address the call from scholars for terminological unity and conceptual clarity (Gupta, 1990; Seddighi, Theocharous, & Nuttall, 2002), Theocharous (2010) reviews and evaluates existing approaches to studying PI and proposes a definition which encompasses the key features of the phenomenon. He describes PI as “a situation where a political system is subjected to challenges or changes in the form of internal conflict, internal change and external conflict. The extent/level of instability is determined by the deviation of any given political event (or a combination of events) from the specific normal pattern of the system in which it occurs.” (Theocharous, 2010, p. 358). PI is related to terrorism in the sense that the latter can be an indicator and an expression of the former (Sonmez, 1998). This said, it is not uncommon for terrorist attacks to take place in politically stable destinations (e.g. Bali, 2005; London 2005; Marrakech, 2010), which is one of the differences between these phenomena. Others may be identified on the basis of a definition of terrorism proposed by Schmid and Jongman (1988, p. 28) who suggest that “Terrorism is an anxiety-inspiring method of repeated violent action ... whereby the direct targets of violence are not the main targets. The immediate human victims of violence are generally chosen randomly (targets of opportunity) or selectively (representative or symbolic targets) from a target population, and serve as message generators. Threat and violence-based communication processes between terrorists (organisations), (imperilled) victims, and main targets are used to manipulate the main target (audience).” This definition highlights that terrorism is concerned with the intentional use of violence against carefully selected targets to communicate a message and satisfy specific aims, for example, targeting civilians to generate media attention, moral repugnance in the target population, and behavioural changes undertaken by the affected (e.g. avoiding travel, or certain places) (Rubin, Brewin, Greenberg, Simpson, & Wessely, 2007; Silver, Holman, McIntosh, Poulin, & Gil-Rivas, 2002) as a means to satisfy political or

Adapted from: Renn (2008).
religiously motivated goals. While media attention may aid the goals of actors such as protestors, for example by generating sympathy amongst international audiences to their goals, its involvement is not the key to achievement of these goals. The dependence of terrorism upon media attention is well captured by the comparison by Ted Koppel, ABC’s host, who said: “without television, terrorism becomes rather like the philosopher’s hypothetical tree falling in the forest: no one hears it fall and therefore it has no reason for being” (Koppel, quoted in Farnen, 1990, p. 104).

While some researchers note that terrorism and PI are not always a major concern for tourists (Fuchs; Uriely, Reichel, & Maoz, 2013; Hunter-Jones, Jeffs, & Smith, 2007; Rittichainuwat & Chakraborty, 2009) the literature is rich in cases where demand for tourism products falls as an outcome of these hazards (see Table 2). Whether or not the magnitude of risk involved in visiting a destination is high, people tend to avoid places they perceive as unsafe because in tourism perception is reality when it comes to decision-making (Santana, 2001). These studies highlight that understanding how people perceive and respond to these hazards remains a serious concern for the tourism industry.

### 2.3. Tourist destination, risk management and media effects

In the context of numerous crises that happen around the world, risk management has become a vital aspect of the way businesses operate within the tourism system. Unmanaged, hazardous events can lead to problematic safety images of tourist destinations, which is a major constraint to a thriving tourism industry (Arana & Leon, 2008; Avraham & Ketter, 2008; George, 2003; Law, 2006; Tallow, 2014). Therefore, it is key that destinations have comprehensive management strategies in place that assess and respond to risks in a manner that protects the safety and security of visitors and staff, and maximises the potential for continuity of business (APEC, 2006). To address this issue, a number of frameworks and guidelines for crisis and disaster management in tourism have been created (APEC, 2006; Henderson, 2004; Ritchie, 2004; Tourism Victoria, 2010).

Media are key to any risk management strategy. Given the potential to misrepresent the magnitude of events and influence the image of destinations, Faulkner (2001) notes that monitoring of media reporting to assess the nature of information that is sent may include tactics such as contradicting the negative messages, perceptions, stereotypes, etc. in reports upon the destination. In essence, such strategy is concerned with the development of messages that correct and neutralise unbalanced portrayals of destinations. Important to these management strategies is the issue of framing and the influence that different representations of hazards may have on the perceived reality of tourist destination safety among audiences in the tourist-generating countries.

#### 2.4. Media coverage – framing effects

In essence, research on framing effects is concerned with the influence of differences in presentation of issues on the attitudes, emotions and decisions of media users (Iyengar, 1991; Pan & Kosicki, 1993; de Vreese, 2005). Framing studies can be separated into two distinct types depending on the kind of framing effect studied (Druckman, 2001b). The first type, concerning ‘equivalency’ or ‘valence’ framing effect, investigates how the use of different but logically equivalent words that highlight positive or negative aspects of an issue (e.g. 5% unemployment versus 95% employment) elicits different responses from individuals (e.g. Kahneman & Tversky, 1984). This type of framing research into wording effects (Druckman, 2001a) is an approach not easily applicable to more complex communicative situations (Sniderman & Theriault, 2004) such as terrorism or PI.

Research on framing in relation to tourism effects typically employs equivalence framing, for example studies of tourists’ attitudes to environmental protection (Kim & Kim, 2014), hotel linen reuse (Blose, Mack, & Pitts, 2015), and hotel booking intentions in response to online reviews (Sparks & Browning, 2011).

The second type, emphasis framing, is ‘closer to “real” journalistic news coverage’ (Nelson, Lecheler, Schuck, & Vreese, 2012, p. 3) and is concerned with the influence on individuals of presenting alternative perspectives that stress different aspects of complex topics (e.g. emphasis on advantages over disadvantages of technology) without the assumption that the information is factually equivalent (Tankard, 2001). The focus of this study is to examine tourists’ perceptions and attitudes in relation to coverage of the complex hazards of terrorism and PI. This suggests the use of an ‘emphasis’ framing approach to framing effects.

de Vreese (2005) notes that from the perspective of emphasis framing, frames are generally seen as coherent packages of information containing a ‘central organising idea or story line that provides meaning to an unfolding strip of events’ (Gamson & Modigliani, 1989: 143). In short, a news frame is an ‘emphasis in

</tbody>
</table>
salience of different aspects of a topic’ (de Vreese, 2005: 53). Through the selection and emphasis on some aspects of a topic above others, journalists present a story to the public within a particular frame of reference (Entman, 2004; Van Gorp, 2007). In this way, certain attributes, judgments and decisions are suggested (Entman, 1993) which helps people classify information to handle it efficiently (Scheufele, 2006). A framing effect is said to occur when, in the course of describing an issue or event, a speaker’s emphasis on a subset of potentially relevant considerations causes receivers to focus on these considerations when constructing their opinions or judgements (Sniderman & Theriault, 2004).

Numerous framing effects studies have manipulated news frames through experimentally prepared news stories to determine their influence upon individual responses. These studies demonstrate how variations in the make-up of messages elicit noticeable variations in audiences’ perceived risk associated with complex issues such as earth quality (Durfee, 2006), nanotechnology (Schütz & Wiedemann, 2008), climate change (Otieno et al., 2014), and invasive species (Otieno, Spada, & Renkl, 2013). Woods (2011) investigated perceived risk in response to fictitious news stories about threat terror which contained different degrees of emphasis on the level of control over hazard and catastrophic potential (Stovic, 1987). He found that his study subjects perceived more risk of terrorism when the danger was associated with ‘radical Islamic groups’ (suggestive of perceived lack of control over potential exposure to an attack), and ‘nuclear’ technology (suggestive of perceived high catastrophic potential of an attack).

2.5. Factors influencing perceived risk in tourism

Tourism literature suggests that perceived risk depends on a range of tourist characteristics. Previous studies found that perceived risk ratings can differ based on factors such as gender (Carr, 2001), age (Floyd & Pennington-Gray, 2004; Kozak, Crotts, & Law, 2007), travel experience (Sonmez & Graefe, 1998a), nationality (Seddighi, Nuttall, & Theocharous, 2001) and personality (Lepp & Gibson, 2003). More recent studies suggest the significance for subjective risk of religion (Adam, 2015; Mansfeld, Jonas, & Cahaner, 2016), knowledge (Sharifpour, Walters, Ritchie, & Winter, 2014), risk tolerance and risk related competences (Williams & Balaz, 2013). Among these, personality traits are often considered to be of particular relevance (Fuchs, 2011; Pizam et al., 2004; Roehl & Fesenmaier, 1992). Perception of risk has been found to depend on degree of novelty seeking (Correia, Pimpao, & Crouch, 2008), self-confidence (Valencia & Crouch, 2008) sensation-seeking (Fuchs, 2011; Lepp & Gibson, 2008; Sharifpour, Walters, & Ritchie, 2013) and multi-trait factors (e.g. extroversion, venturesomeness) (Reisinger & Valivento, 2005). A variable that has received less attention in this context is the psychographic typology of Plog (1974; 1991), who divided tourism consumers into two broad groups of allocentrics and psychocentrics (with additional near-psycho-centric, mid-centric, and near-allocentric groups). According to Plog, psychocentrics are characterised by being anxious within their daily lives, risk averse, and preferring to travel on package tours to familiar and commonplace destinations. Moreover, they tend to visit sun-and-fun destinations which are consistent with their preference for low activity levels (Plog, 2001). In contrast, allocentrics prefer unstructured trips to unusual places and more contact with local cultures. They are more confident, less anxious, motivated by novelty, discovery, and seek active vacations that allow them to explore the physical and cultural worlds around them (Plog, 2002). In reality the situation is a lot more complicated, as most people are mid-centric, that is, they combine elements of both types, and therefore distinct types are difficult to identify.

A number of studies used Plog’s system to investigate tourist preferences, which resulted in some support for this personality factor (Griffith & Albanese, 1996; Nickerson & Ellis, 1991; Weaver, 2012). Others found no association between Plog’s personality types and destination preferences (Litvin, 2006; Smith, 1990). While the ability of the instrument to predict destination choices has received much attention, its use in understanding variances in tourists’ risk perception in responses to hazards deserves more research.

In light of the outlined gaps in the literature on the relationship between media framing, terrorism, PI and tourism risk perception, the study set out to address the following research questions:

**RQ1:** Does leisure tourists’ perceived risk depend on media frames concerning the magnitude of terrorism and political instability risk (high or low)?

**RQ2** Does leisure tourists’ perceived risk depend on media frames concerning event type (terrorism or PI)?

**RQ3** Does leisure tourists’ perceived risk depend on the degree of allocentrism (allocentric, midcentric, or psychocentric).

3. Methods

An online survey-based experiment was employed with a focus on the causal link between news media frames of terrorism and PI, and leisure tourists’ perceived risk. A mixed factorial 2 (hazard type: terrorism or PI) x 2 (risk framing: risk amplifying or risk attenuating) between-subject design was employed (see Table 3). The sample of experiment participants was obtained from a questionnaire-survey (N = 475) that preceded the experiment. All respondents identified themselves as leisure tourists. A total of 160 respondents (N = 160) expressed an interest in participating in a follow-up study by providing an e-mail address. Apart from providing a sample for the experiment, the first questionnaire survey, which measured UK leisure tourists’ risk perceptions, holiday choices and a range of demographic and psychographic factors, identified tourist characteristics (i.e. degree of allocentrism, age, gender) relevant to the dependent variable (i.e. perceived risk). The personality variable was measured with a scale comprised of 8 items adapted from Jackson and Inbakaran (2006). Each of the items represented a different aspect of the tourist personality, i.e. the need for structure, familiarity/novelty, off-the-beaten-track, reliance on the tourism industry, venturesomeness, intellectual curiosity, activity, and openness to other cultures, which was phrased as a statement referring to tourists’ holiday preferences. The data were then used to control for relevant variables in the experiment. Following the procedure used in media effects studies (Wimmer & Dominick, 2011), participants were matched on relevant variables (degree of allocentrism, age, gender) to create four groups before being assigned at random to different treatments.

On the 6th of March 2013 the participants (N = 160) were sent an e-mail containing a link to an online survey questionnaire. Each group received a different scenario, i.e. one of Terrorism A, Terrorism B, PI A or PI B. After the initial campaign, 7 e-mails were returned as non-deliverable and identified as non-existing. The

final number of confirmed e-mail deliveries was reduced to 153 (N = 153).

3.1. Stimulus material and measures

The respondents were placed in a scenario of considering a holiday in a non-specific country. Role playing is a commonly adopted method in experimental designs (Petty et al. 1991; cited by Jun & Vogt, 2013). The reason for the de-contextualised scenario was to exclude the influence on dependent variables of the potentially confounding effects of respondents’ attitudes and feelings towards the country and prior visit experiences. After reading the scenario the respondents were invited to read a short news article about an incident in this destination country and rate their perceived risk associated with visiting the destination. Perceived risk was measured only post-test to avoid cueing the respondent to the specific goal of the media stimulus. Similar experimental designs have been used in past research on framing effects to avoid sensitising participants (e.g. Lecheler & de Vreese, 2010; Maoz, 2012). No control group was used in the experiment. Each of the four treatments acted as a control group for the other three treatments, as it manipulated message elements that the other treatments did not.

With respect to the stimulus material, the news article was produced in four alternative versions. Following common practice employed in experimental framing studies to separate content from frames (e.g. Iyengar, 1991; Price et al. 1997; Valkenburg et al. 1997; cited in; Schuck & de Vreese, 2006), versions about terrorism and PI were designed in a fashion that holds the factual base of phenomena. Consequently, different characteristics associated with these distinct hazardous events were incorporated into two pairs of fictitious articles. Within each pair, the articles differed in the hypothesised direction of their influence on dependent variables of interest. Event descriptions should not be treated as representative of any case of PI or terrorism as these may involve different targets, tactics, locations etc. The goal of manipulation was to increase the likelihood of activation in audiences of different thoughts and perceptions, as it manipulated message elements that the other treatments did not.

With respect to factor 1 (event type), terrorism and PI have been identified in the tourism literature as similar but also distinct phenomena. Consequently, different characteristics associated with these distinct hazardous events were incorporated into two pairs of fictitious articles. Within each pair, the articles differed in the hypothesised direction of their influence on dependent variables of interest. Event descriptions should not be treated as representative of any case of PI or terrorism as these may involve different targets, tactics, locations etc. The goal of manipulation was to increase the likelihood of activation in audiences of different thoughts and feelings associated with these events, and potentially different judgments of risk. To achieve this the event descriptions were designed in a manner that resembles hazardous events that received attention in UK national newspapers and were identified by reporters as either PI or terrorism. With respect to PI, given that data was collected in March 2013, arguably, the most prominent and recent event preceding this date were the January 2011 protests in Egypt. A search on the Lexis Nexis UK database between (28.01.2011 and 28.03.2011) with keywords (‘Egypt’; ‘Political Instability’, ‘Unrest’) resulted in 481 hits. On the basis of this content, PI was described as an incident involving protests in a city centre location, human casualties, some potential spread of protests to other locations and no advice from the FCO against travel to the country.

With respect to terrorism, two prominent events preceding the data collection period were the April 2011 bombing in Marrakech and July 2011 triple attack in Mumbai. The following searches were performed to source articles about the events in 1) Marrakech: Keywords (‘Marrakech’; ‘Terror!’) between (28.04.2011 and 28.06.2011) resulted in 22 hits, and 2) Mumbai: Keywords (‘Mumbai’; ‘Terror!’) between (13.7.11 and 13.9.11) resulted in 41 hits. Next, terrorist attack was conceptualised as an incident involving a bomb explosion in a city centre location, with human casualties, unknown perpetrators and no advice from the Foreign and Commonwealth Office (FCO) against travel to the country.

Manipulations of factor 2 (risk framing) were guided by a theoretical assumption that different portrayals of qualitative features of terrorism and PI will have different effects on tourists’ risk perception. In this sense, factor 2 represents the message framing with two levels, i.e. frame intended to amplify perceived risk (A), or frame intended to attenuate perceived risk (frame B). Each frame embedded within an article involved manipulation of message elements concerning four qualitative features of terrorism and PI (see Tables 4 and 5). The qualitative dimensions selected for this exploratory experiment that may indicate different levels of magnitude of risk (e.g. level of control) were guided by research on risk perception. What needs to be noted is that the message elements selected are not an exhaustive list of risk indicators that may be used in reporting on terrorism and PI. Rather, they are a set of potential elements of news reports that may influence the level of audiences’ perceived risk associated with visiting an affected area. The specificity of the message elements employed within versions A and B, and their expected direction of influence, are explained and justified in the following sections.

In the case of terrorism, the four qualitative dimensions of the hazard that involved different levels of emphasis on information potentially relevant to the judgment of magnitude of risk were (see Table 4): 1) targets of attack, 2) suspected perpetrators, 3) location of explosion and threat of further attacks, and 4) event atmosphere and confidence level.

With respect to targets of attack, the extent to which a hazard receives media attention and possibly affects audiences’ perceived risk is partly dependent on who the violence, or its threat, is directed at. In other words, it isn’t only about ‘body counts’ but also about ‘whose body counts’ (Kritzinger, 2009). Media coverage which puts emphasis on victims that are particularly relevant to audiences, for example, tourists of certain nationality, religion etc., as opposed to ‘others’ such as foreign military units, may be

</tbody>
</table>
The fourth dimension of risk amplification/attenuation concerns how commentary from the general public (vox populi, or ‘vox pops’) influences perceptions of event atmosphere and confidence level. Vox pops (or any other news source) can be used to frame an issue by supplying background information or story suggestions (Matthews, 2010). Drawing on findings from the psychometric tradition of perceived risk, new risks (e.g. unknown technologies) are perceived as involving more risk than ones that audiences are familiar with. Using this logic, version A of the article emphasises the ‘newness’ of the problem as perceived by the local public, and its negative consequences on individuals’ confidence in response to the event. In contrast, version B presents the information from a balanced point of view with an emphasis on the habituation of the members of the public to the problem, and their resilience. As such, the frames represent two distinct ways of reacting to terrorism, i.e. with fear or determination, which may suggest to readers which course of action is most suitable.

In the case of PI, the four dimensions were: 1) violence, 2) commentary on degree of socio-political tensions, 3) geographical spread and consequences, 4) disruptions to transport network (see Table 5).

The first dimension of the frame employed in the article concerned the presence or absence of violence. While the challenge to a political system can be sought through peaceful means such as protests or strikes (Scarborough, 1998) PI is often associated with violence, whether civil, wars, military coups or riots (Hall & O’Sullivan, 1996). Exposure of audiences to reports of violence may result in risk perceptions disproportionate to the actual probability of harm, a phenomenon Sunstein (2003) refers to as probability neglect. Therefore, in describing the nature of the confrontations, the word “violent” is employed in version A of the article, expecting to add to the concern of the audience, as opposed to its absence in version B.

Next, socio-political tension, seen by Siermann (1998) as a common thread to different expressions of PI, was used as another dimension of PI that can be used by individuals to arrive at risk judgments. However, it can be argued that the ability of tourists to judge personal risk on the basis of the extent of underlying socio-political tensions and the ability of the government to maintain social order is likely to be limited due to the complexity of such issues. In this context, a news frame may simplify the process and enable conclusions to be drawn. Therefore, portraying the event as being characterised by a ‘threatening atmosphere of high tension’ in version A versus “isolated acts of frustration” in version B may promote different degrees of perceived risk. As such, the degree of social tension as captured in vox pops pertains to the level of control and ability to avoid the potential problems a tourist may have in an affected destination.

In a similar vein, the frame dimension concerning the geographical spread and consequences of the event pertains to the level of control and so has implications for the magnitude of risk perception. Therefore, version A of the article stresses the possibility of unrest spreading to areas across the country, and its
"serious consequences for public safety and order". Conversely, in version 'B', emphasis is placed on a prediction that events will remain "contained to city squares" and other areas will remain "calm and not affected", and is expected to produce lower ratings of risk.

The fourth dimension of the frame employed concerns disruptions to the transport network. It is proposed that an emphasis placed on the possibility of transport "delays and cancellations" in version A of the article would be expected to heighen tourists’ risk perception, as opposed to an absence of such emphasis in version B.

**Perceived risk** was measured only after participants’ exposure to the article treatment on a 5-point Likert scale: from 1 = Very Worried, to 5 = Not at all worried. No pre-test of perceived risk was taken due to a concern over sensitising the participants to the objective of the experiment. Moreover, since the country context was non-specific, i.e. respondents had no perceptions of risk present in the country (or other feelings and attitudes which may have influenced the judgment), one measure was sufficient to observe the impact of the article.

3.2. Participants

A sample of UK leisure tourists was used in the experiment. The final groups that responded to each of four news report scenarios were as follows: Terrorism A = 30, Terrorism B = 34, PI A = 28, PI B = 32. The sample comprised of 60 (48.4%) males and 64 (51.6%) females. The ages ranged from 18 to 65 years old and over, with ‘45–54’ being the largest age category (26.6%), followed by ‘35–44’ (25%), and ‘25–34’ and ‘55–64’ (both 17.7%). ‘65+’ and ‘18–24’ were the smallest age categories with 7.3% and 5.6% respectively. The data reflect the UK population of outbound holidaymakers measured between 2005 and 2009 (ONS, 2011). Using psychographic profiles established on the basis of items suggested by Weaver (2012) and Jackson and Inbakanar (2006), the sample included 21 (16.9%) Psychocentrics, 74 (76.6%) Midcentrics, and 29 (23.4%) Allocentrics. The data were analysed using Kruskal-Wallis and Mann Whitney U tests.

4. Results

4.1. RQ1

A non-parametric Kruskal-Wallis test was run to examine the differences in perceived risk between the groups of respondents exposed to different article versions. The result of the test was significant at p < 0.000 level. Therefore, to test for differences between article pairs (risk amplifying) and B (risk attenuating), a post-hoc Mann-Whitney test was employed with the confidence level set at p < 0.025. It was hypothesised that the tourists exposed to article version A would perceive more risk than those who had read version B.

The results (Table 6) were significant in both the terrorism and PI pairs, that is, as hypothesised, the risk amplifying version of articles caused significantly higher risk concerns (lower scores) than risk attenuating version B. Therefore, the null hypothesis can be rejected. The variations in the presentation of the different aspects, or indicators, of risk produced an effect on the tourists’ responses. The difference in tourists’ risk perception between the articles in the PI pair was larger (r = −0.55) than in the terrorism pair (r = −0.31).

4.2. RQ2

A Mann-Whitney test was employed to examine the difference in risk perception between the frames concerning the event type, i.e. PI versus terrorism. The results (see Table 7) indicate a statistically significant difference of low to medium strength (r = 0.337) between terrorism and PI in the B pair (risk attenuating frame). A reverse relationship was expected in the A version of the articles, where a severe version of PI, such as the recent events in Egypt or Syria, might be expected to be more intimidating than a terrorist attack which specifically targets tourists or popular tourist areas. While this may also be complicated by other factors such as, for instance, weapon type, in general a terrorist attack, such as a bombing, shooting or kidnapping, represents a different degree of threat to a large scale event of PI, both in terms of the potential for physical harm, the geographical spread of vulnerable zones and the length of time in which a destination may be vulnerable to such actions. This, however, was not supported by the findings of this study.

4.3. RQ3

A significant result (p < 0.000) was derived from application of a Kruskal-Wallis test comparing the three personality types across all four versions of the article. To follow up on this result, a series of Mann-Whitney tests were performed between the extreme groups of the psychocentrics and allocentrics in each article condition expecting the latter group to score higher (i.e. lower perceived risk). The results (see Table 8) point to differences in the expected direction, but the only significant result was noted with respect to the Terrorism A article (p < 0.005). Interestingly, when the perceived risk of the allocentrics and psychocentrics was compared across all the article groups, a highly significant result (p < 0.001) was obtained. That is, regardless of the article read, the allocentrics perceived less risk (r = −0.48) than their psychocentric counterparts. This suggests that psychocentrics are more sensitive than allocentrics to message elements which suggest a deviation from an acceptable level of risk. This finding is in line with a “cognitive-transactional” model of media effects (Perse, 2001, p. 51) which suggests that the effect of media content may be moderated by audience variables such as schema make-up and specific beliefs and attitudes.

An effect on leisure tourists’ risk perception was observed as a result of the exposure of audiences to different frames concerning the magnitude of terrorism/political instability risk. Readers of article versions A (risk amplifying) perceived more risk than those who read versions B (risk attenuating), regarding both terrorism and PI, albeit the differences were larger in the PI group. Specifically, the result demonstrates that the emphasis on some aspects of a source of risk, to the exclusion of others, may result in different risk perceptions associated with visiting a destination among the message recipients. This finding supports the results of framing effects studies carried out outside the tourism consumer behaviour context (e.g. Schuck & de Vreese, 2006; Woods, 2011), and addresses the calls for research on framing effects in tourism (Liu & Pennington-Gray, 2015), and specifically on the relationship between the media coverage of hazards and destination perceived risk (e.g. Schroeder, Pennington-Gray, Kaplanidou, & Zhan, 2013; Sonmez & Graefe, 1998a).

Interestingly, the differences in perceived risk between readers of risk amplifying and attenuating article versions were smaller in the terrorism pair. This suggests that in judging the risk associated with visiting foreign countries for leisure purposes, tourists may be particularly sensitive to any information about terrorism due to the discretionary nature of holiday activity and a limited knowledge of the country. In this context, they may be less motivated to consider incident characteristics, such as the perpetrators and the targets, and instead make a risk judgment on the basis of the fact that an attack has occurred and another one is possible. This explanation is contrary to the findings of the experimental research on terrorism of Woods (2011), which show that differences in the information concerning the perpetrators (i.e. ‘Islamic extremists’ versus other terrorists) significantly influence perceived risk. However, notably, this research was conducted in a different context, namely the risk of terrorism to US citizens, which may be completely different to assessing the risk to oneself in association with visiting a foreign country. In the case of PI, the larger difference may be due to the fact that while information concerning large-scale unrest likely brings to mind a range of dramatic images (e.g. violent unrest in Egypt, Syria etc.) and scares people, the portrayal of an event as localised and under control reassures people by conveying a picture of reasonably safe conditions.

The risk-attenuating frame had more impact on perceived risk in relation to PI than in relation to terrorism. This suggests that despite variations in event characteristics, a terrorist attack may be a much more deterring factor, at least in the short term, than a case of PI which appears to be limited in scope. No difference in risk perception between terrorism and PI was observed in version A of the article, where the risk-amplifying frame might be expected to have produced higher levels of anxiety in relation to PI. This is contrary to the findings of Saha and Yap (2013) who find that political events have a more deterring effect on the tourism industry than terrorist attacks. The data of this study may be explained by the perceived random character of terrorist attacks which implies low ability to control the severe consequences, and hence leads to judgements of greater personal risk.

Notably, the study indicates that the risk perceived by respondents post-reading of the article about a hazard depends on their psychographic characteristics. In their study of the influence of Uganda’s tourism website on tourists’ perceived risk, Lepp, Gibson, and Lane (2011) found no relationship to Cohen’s tourist types, a construct related to allocentricity. Here, however, the allocentric recipients were less concerned about terrorism and PI post reading of the article versions than the psychocentrics. This supports the notion that the impact of risk communication depends not only upon the content of the message but also the characteristics of the audience (e.g. Lecheler et al. 2009), in this case, the tourist personality profile.

### 5. Discussion

In terms of practical implications, on the one hand, the media effect found in this study poses challenges to tourism marketers who wish to minimise the negative effect of media coverage of hazards such as terrorism and PI. On the other, it stresses the need to further research the formats of presenting the information. Findings indicate that when judging the risk involved in visiting a country subject to a terrorist attack, tourists may be less sensitive to information about the characteristics of the event and draw conclusions mainly on the fact that the event took place. Secondly, the clear disparity in perceived risk between the readers of the two PI articles demonstrates that while tourists are relatively unconcerned about unrest portrayed as contained to small or non-tourist areas, its extreme expression is a source of grave concern. These findings are of importance to communication practices in a post-

### 6. Conclusion

The findings enhance the understanding of the relationship between perceived risk, the media, and tourist consumer behaviour by empirically supporting the validity of the framing theory of media effects (Scheufele, 1999). Drawing on theories of the psychometric paradigm of risk (Slovic, Fischhoff, & Lichtenstein, 1986), the exploratory experiment established that the effects were not uniform across recipients and were contingent upon audience characteristics, most notably tourist personality type. Importantly, this aspect of the media and perceived risk interaction points toward a two-directional relationship, which recognises both the power of the media to influence message recipients and the power of audiences to oppose and negotiate the messages. This research proposes that marketers can influence the way tourists attend to risk messages and evaluate tolerability of risk involved in holidays.

Methodologically, the experimental design employed in this study contributes to the growing body of experimental work in the study of consumer behaviour in tourism, and to our best knowledge is the first experimental study of framing effects on perceived risk in tourism. Jun and Vogt (2013) and Cohen, Prayag, and Moital (2014) note that experimental research designs are seldom used in travel and tourism research, which is dominated by the cross-sectional approach. Despite calls for their use in tourism perceived risk research (e.g. Chew & Jahari, 2014; Roehl & Fesenmaier, 1992), examples of studies that employ such designs are still rare (e.g. Lepp et al. 2011). Future studies that employ an experimental design could investigate the potential effects of media frames in a more dynamic context, i.e. with the use of images and audio. A further area for research would be to adopt a longitudinal approach to studying media effects, rather than a one-shot media exposure approach.

Notably, the study indicates that the risk perceived by respondents post-reading of the article about a hazard depends on their psychographic characteristics. In their study of the influence of Uganda’s tourism website on tourists’ perceived risk, Lepp, Gibson, and Lane (2011) found no relationship to Cohen’s tourist types, a construct related to allocentricity. Here, however, the allocentric recipients were less concerned about terrorism and PI post reading of the article versions than the psychocentrics. This supports the notion that the impact of risk communication depends not only upon the content of the message but also the characteristics of the audience (e.g. Lecheler et al. 2009), in this case, the tourist personality profile.
disaster context, especially the aftermath of terrorist attacks and PI. Moreover, in recognition of tourist characteristics that determine differences in perceived risk, catering for experienced tourists with allocentric tendencies may be particularly useful for destinations in the post security crisis phase. To this end, destination marketers can tailor their offers to match the needs of this segment by providing novel, active, culturally stimulating and excites experiences that increase the propensity to rationalise risk.

There are limitations in the research design used. To control for the potential confounding effects in the experiment that tourists’ ideas and feelings about a destination may have on the perceived risk, the relationship between the news reports and perceived risk was investigated in a scenario of a hypothetical destination. Whereas a destination that tourists recognise would have been ideal, arguably the choice made by the researcher represents a common scenario where tourists make holiday decisions with imperfect knowledge of destinations. Furthermore, while allowing for the studying of responses of a diverse sample of respondents, the online survey-experiment was also associated with limited control over the participants, which is typically overcome by a laboratory approach. Following procedures employed by Jun and Vogt (2013), to control for the issue of respondents attending to other information during participation, responses from those who spent more than 20 min on the study were excluded from analysis.

With respect to the sample, the study focused on British tourists, which may not be representative of potential responses of other nationalities to similar fictitious stories. Future studies could focus on samples of different nationalities or those that comprise of two or more nationalities. Other questions require more attention. Due to the design employed in this study it is not possible to isolate the influence on perceived risk of, for example, nationality of perpetrators. Future studies could seek to manipulate this aspect of the message to seek to understand whether attacks and/or threat of further attacks on tourists of the same nationality have a stronger effect on perceived risk than those directed at ‘others’.

Moreover, given the sample of the study and the fact that a number of recent attacks and/or warnings in major European destinations (e.g. France, Belgium, Germany) were perpetrated by the Islamic State (IS), rather than al Qaeda, it can be argued that the focus in this paper on the latter actor constitutes another limitation of this research. This said, at the time of data collection (March 2013) IS was an unknown entity in Europe, hence why al Qaeda was chosen as a group likely to be recognised by respondents and taken into account in making risk judgments. Future studies could focus on stories concerning other perpetrators and the relative impact of such information on tourists’ judgments.

Finally, beyond the message content, the stories presented to respondents were not attributed to any specific news source or presented in different news outlets e.g. newspapers, social media, etc. Future studies could seek to address this by manipulating these variables.
