23 **Abstract**

24 As zebrafish embryos never been cryopreserved, we developed a protocol to store zebrafish embryos
25 (50% epiboly- 5.3 hpf) for up to 18 h at 0° C. Initial experiments to optimise cryoprotectant solution
26 demonstrated improved embryo hatching rate following chilling at 0°C for 18 h with 1 M MeOH +
27 0.1 M sucrose (56 ± 5%) compared to other combination of methanol (0.2-, 0.5 M) and sucrose (0.05-,
28 0.1 M). This combination of cryoprotectants that protects against chilling injury was further tested to
29 assess its impact on *sox* gene and protein expression. Significant decreases in *sox3* gene expression
30 were observed in hatched embryos that had been chilled for 18 h in 1 M MeOH + 0.1 sucrose
31 compared to non-chilled controls, however expression of both *sox2* and *sox3* proteins was unaffected.
32 Significant decreases in *sox2* protein expression were however observed in embryos that had been
33 chilled without cryoprotectants and these embryos also had lower hatching rates than those chilled
34 with the optimal cryoprotectant solution. We therefore conclude that the cryoprotectant combination
35 of 1 M MeOH + 0.1 M sucrose facilitates chilled storage of early stage (50% epiboly) zebrafish
36 embryos for up to 18 h without compromising transcriptional response.

48 **1 Introduction**

49 Chilled storage of zebrafish embryos is becoming increasingly important due to the fact that
50 cryopreservation of fish embryos is still a challenge due to their structural limitations¹. Storage of
51 aquatic embryos at low temperatures for extended periods has important applications in aquaculture
52 and fish farming. Chilled storage has practical applications in fish embryo handling e.g. for embryo
53 transportation between fish farms for genetic improvement programs. However fish embryos of
54 several species including zebrafish have been shown to be chilling sensitive²⁻⁵. Zhang and Rawson³
55 showed that early stage zebrafish embryos were more chilling sensitive than later stages but the
56 methanol solution containing sucrose in an enhanced survival of heartbeat stage embryos was
57 achieved following chilled storage for 18 and 24 h at 0°C. Higher survival had also been seen in
58 common carp (*Cyprinus carpio L.*) embryos 12 hour post fertilization (hpf) when they were chilled at
59 zero and sub-zero temperature for 12-72 h in presence of MeOH (1.5 M) and sucrose (0.5 M)
60 compare to using these cryoprotectants (CPA) separately or without CPAs⁶. However, all these
61 studies are based on the results obtained on embryo hatching/survival rate and did not provide
62 information on molecular stability i.e. gene and protein expression. It has been shown that storage of
63 zebrafish embryos using propylene glycol in the liquid nitrogen even for 1 min resulted in damage of
64 mitochondria, disorganisation of ribosomes and plasma membrane of the yolk syncytial layer⁷. In our
65 previous studies⁸, significant decreases in *sox2* (up to 4-fold) and *sox3* (up to 3-fold) were observed
66 in embryos that had been chilled for up to 180 min at 0 ° C. Therefore information on the effect of
67 chilling and cryopreservation on embryos at the molecular level is important in designing protocols
68 for successful chilled storage and cryopreservation of the embryos.

69 In recent years, zebrafish has become an important animal model in scientific research. Zebrafish is
70 used extensively for developmental biology studies such as determination of the embryonic axis⁹, cell
71 lineage analysis¹⁰, formation of the central and peripheral nervous system¹¹, cardiovascular
72 development¹² and differential regulation of gene expression¹³. Studies have also revealed a close
73 relationship between the zebrafish and human genomes and it has been proposed that zebrafish could
74 be a bridge between study of human disease and development due to the significant homology

75 between zebrafish and human genomes ¹⁴. In the current study, *sox* genes have been used as a marker,
76 due to their multi-functional roles during development ¹⁵⁻¹⁷ to evaluate the effect of long term chilling
77 on gene and protein expression.

78 The aim of the present study was to enhance hatching rates of early stage zebrafish embryos by
79 identifying conditions that do not have an impact on *sox* gene expression. Studies were carried out to
80 investigate the effect of chilling and warming on gene and protein expression in the embryos that had
81 been chilled with cryoprotectant mixtures for up to 18 h and warmed and cultured until the hatching
82 stages.

83 **2 Materials and methods**

84 **Zebrafish maintenance and embryo selection**

85 Adult zebrafish 12-14 weeks old were maintained in 40 litre glass tanks at 28° C. The males and
86 females were kept at a ratio of 1:2 and a 12 hour light/dark cycle was used. Fish were fed three times
87 a day with TetraMin[®] (Tetra, Germany) flake food and once a day with freshly hatched brine shrimp
88 (*Artemia salini*) (ZM systems, UK). Embryos were collected in the morning and kept in a 28° C water
89 bath until the desired stage was reached. Embryonic stages were determined using light microscopy
90 (Leica MZ95, Germany) according to the morphology described by Kimmel ¹⁸.

91 **Experimental Design**

92 **Experiment 1: Assessing the effect of 18 h chilling on hatching rate in zebrafish embryos in the** 93 **presence of sucrose and MeOH mixture**

94 Embryos (50% epiboly) were chilled at 0°C for 18 h with different concentrations of MeOH (0.2 M,
95 0.5 M and 1 M) in combination with sucrose (0.05 M, or 0.1 M). Embryos (20 embryos/ 3mL
96 cryoprotectant) were chilled at 0°C in a crushed ice bath for 18 h in test tubes and the temperature was
97 maintained using crushed ice ¹⁹. After chilling, the cryoprotectant solution was replaced with
98 Embryonic medium 2 (EM2, 15 mM NaCl, 0.5 mM KCl, 0.27 mM CaCl₂, 1 mM MgSO₄, 0.27 mM
99 NaHCO₃, 0.15 mM KH₂PO₄, 0.05 mM Na₂HPO₄) and the test tubes were quickly placed into a

100 27±1°C water bath. Embryos were washed three times with 27±1°C EM2 and then incubated at
101 27±1°C until they hatched. Control embryos were kept at 27±1°C throughout. Hatching rates were
102 then calculated and all experiments were performed three times (20 embryo/treatment) in triplicate
103 using total of 1260 embryos. Embryo hatching rates were examined at 72 h post treatment according
104 to morphological changes described by Kimmel¹⁸. Embryos were considered to be hatched when
105 their chorion was missing, there were no obvious signs of malformation, and there was natural
106 movement with a functional heartbeat. Embryos were considered unhatched and removed if they
107 showed no sign of cell differentiation, yolk coagulation, lacked tail formation, had detached tails
108 and/or if they remained in the chorion²⁰.

109 **Experiment 2: Assessing the effect of 18 h chilling on *sox* gene expression in zebrafish** 110 **embryos**

111 The optimal cryoprotectant mixture 1 M MeOH + 0.1 was identified and used in this study to
112 investigate the effect of chilling on embryo gene expression. Embryos at 50% epiboly stage were
113 chilled at 0° C for 18 h in the optimal cryoprotectant mixture (1 M MeOH + 0.1 M Sucrose) as
114 described in experiment 1. RNA from each treatment category (0 h, 18 h chilled, 18 h control and 18
115 h chilled in cryoprotectant mixture and control at 27 °C) was then extracted and cDNA was produced
116 and diluted at a ratio of 1:2 with molecular biology grade water (Sigma, UK) for use in real time
117 PCR, as described below. Each experiment was repeated three times, with three groups of five
118 embryos per treatment category being used for each replicate (n = 225).

119 **Experiment 3: Assessing the effect of 18 h chilling and warming on *sox* (*sox2*, *sox3* & 120 *sox19a*) gene expression in zebrafish embryos**

121 This experiment was performed in order to identify the *sox2*, *sox3* and *sox19a* gene expression patterns
122 in chilled embryos after warming and subsequent incubation upto the hatching stage. 50% epiboly
123 staged embryos were chilled in the optimal cryoprotectant mixture (1 M MeOH + 0.1 M sucrose) as
124 described in experiment 1 and warmed at 27±1°C. They were then incubated at 27 ± 1°C until they
125 reached the hatching stages. RNA from different stages [before chilling (0 h), after chilling (18 h), 20

126 somites, heartbeat and hatching] was extracted and cDNA was produced as per experiment 2. cDNA
127 was diluted at ratio of 1:2 with molecular biology grade water (Sigma, UK) for use in real time PCR.
128 For each stage, three different biological samples (5 embryos/tube) were used. Each experiment was
129 repeated three times (n=225). Experimental controls were kept at $27\pm 1^{\circ}\text{C}$ in a water bath for the
130 equivalent time period.

131 **Experiment 4: Assessing the effect of 18 h chilling and warming on *sox2* and *sox3*** 132 **protein expression in zebrafish embryos**

133 In order to further understand whether the gene expression patterns observed in experiment 3 had an
134 impact on translation. Protein expression studies were carried out for *sox2* and *sox3* following 18 h
135 chilling and after hatching. Chilling and warming was carried out as described in experiment 3.
136 Following treatment, proteins were extracted immediately from 75 embryos per treatment category (0
137 h , 18 h RT , 18 h chilled, 18 h chilled with cryoprotectant solution – for 18 h chilled time points) and
138 hatching stages (18 h RT, 18 h chilled-warmed, 18 h chilled with cryoprotectant solution and warmed
139 – for 18 h chilled and warmed time points) as described below and stored at -80°C .

140 **RNA extraction and DNase treatment**

141 RNA was extracted from embryo samples using RNAqueous Micro RNA Isolation Kit (Ambion, UK)
142 according to the manufacturer's protocol. This protocol also includes a DNase I treatment step. RNA
143 was stored at -80°C until further use and was checked for quantity and purity using a Biophotometer
144 (Eppendorf, UK) at 260 nm and 280 nm.

145 **Reverse transcription**

146 RNA (1 μg) was transcribed using Precision qScript Reverse Transcription Kit (Primerdesign Ltd,
147 UK) according to the manufacturer's protocol. For conventional PCR, undiluted cDNA was used in
148 subsequent steps. For real time PCR experiments, cDNA was diluted 1:2 in molecular biology grade
149 water (Sigma, UK) and stored at -80°C .

150 **Conventional PCR Analysis**

151 The PCR reactions consisted of NH₄ PCR buffer (Bioline, UK), 200 μM dNTP (Bioline), 1.5 mM
152 MgCl₂ (Bioline), 2 U BIOTAQ™ DNA polymerase (Bioline), 0.5 μM each primer (see Table 1), 1 μg
153 RNA template and PCR water up to a value of x. Standard conditions for PCR were initial
154 denaturation at 94° C for 5 min, 40 cycles of 94° C for 30 sec , annealing temperature (see Table 1)
155 for 30 sec and 72° C for 30 sec, followed by 10 min additional extension at 72 °C. The PCR products
156 were run on 2% agarose gels and stained with ethidium bromide (0.5 μg/mL, Sigma, UK).

157 **Generation of standards for real time PCR**

158 The standards for real time PCR of *sox2*, *sox3* and *sox19a* along with housekeeping genes EF1-α and
159 β actin²¹ were produced using conventional PCR as described above. The primer sequences are given
160 in the Table 1. DNA was isolated from excised gel bands using the EZNA Gel extraction kit (Omega
161 Bio-Tek through VWR, UK) according to the manufacturer's instructions. The isolated DNA was
162 quantified using a Biophotometer (Eppendorf, UK) at 260 nm and diluted to 2 ng/μl followed by 10-
163 fold serial dilutions to generate standards for real time PCR.

164 **Quantification of *sox2*, *sox3* and *sox19a* using real time PCR**

165 Real time PCR was performed on a RotorGene 6000 cyclor (Corbett Research, UK) using a 72 well
166 rotor to quantify the expression levels of *sox2*, *sox3* and *sox19a*. Reaction tubes contained 7.5 μl of
167 sensimix 2X reaction buffer (containing heat activated DNA polymerase, Ultrapure dNTPs, MgCl₂,
168 SYBR® Green I), 333 ηm of each primer (see Table 1) and 2 μl of cDNA sample, made up to 15 μl
169 with PCR water. The reaction conditions were 95° C for 10 min, 50 cycles of 95° C for 10 sec, the
170 appropriate annealing temperature (see Table 1) for 15 sec and 72° C for 15 sec. Data were acquired
171 on the FAM/SYBR channel at the end of each extension step. Melt curves were analysed to check for
172 the absence of mispriming and amplification efficiency was calculated from a standard curve
173 (efficiencies ranged from 0.8 to 1.0 and R² values from 0.99 to 1). The possibility of genomic DNA
174 amplification was eliminated by use of primers that crossed introns. Relative gene expression levels
175 were calculated using the two standard curve quantification method in the Rotorgene software²². Ef1

176 α and β actin were used as housekeeping genes (HKG) for this study as these genes were previously
177 shown to have the highest stability during chilling of zebrafish embryos²¹.

178

179 **Protein expression analysis**

180 **Extraction of protein and quantification:** Embryos (75 embryos/treatment) were washed twice with
181 EM2. Before being subjected to protease treatment (2 mg/ml, Sigma-Aldrich) for 10 min to partially
182 digest the chorions. Loosened chorions were then removed by gentle suction and friction, resulting
183 from pipetting the embryos up and down. Dechorionated embryos were washed a further three times
184 with EM2 before being transferred to a 1.5 ml tube. 100 μ l of protein extraction buffer (0.125 M Tris-
185 HCl, 4% SDS, 20% glycerol) was added to each tube and samples were heated to 95°C for 10 min.
186 Following heating, samples were vortexed and centrifuged at 13,000 x g for 10 min and protein
187 containing supernatants were collected. Isolated proteins were quantified using the QuantiPro™ BCA
188 Assay Kit (Sigma-Aldrich) according to the manufacturer's instructions.

189 **Western blot and immunostaining:** Extracted protein was separated using sodium dodecyl sulphate
190 polyacrylamide gel electrophoresis (SDS-PAGE). Proteins (40 μ g) were loaded on 4% stacking gel
191 and separated on 10% resolving gels at 200 V for 40-60 min. Proteins were then transferred to PVDF
192 membranes using the semi dry method (BioRad, UK). Immunoblotting was carried out using an Anti
193 rabbit WesternDot 625 Western Blot Kit (Invitrogen, W10132). The membrane was blocked in 10 ml
194 WesternDot blocking buffer for 1 hour at room temperature. Following blocking, membranes were
195 incubated with 10 ml primary antibody solution (dilution 1:1000) overnight at 4°C on a gel rocker.
196 Primary antibodies against *sox2* (Abcam, Cambridge, UK), *sox3* (Eurogentech, Belgium) and *β -actin*
197 (Eurogentech, Belgium) were used at 1:1000 concentration diluted in PBS. The membranes were then
198 washed 3 times for 10 min with WesternDot Wash buffer. Following washing, the membranes were
199 incubated with 10 ml Biotin-XX-Goat anti-rabbit solution (1:10000) for 2 hours at room temperature.
200 After secondary antibody incubation, the membranes were further washed 3 times. The membranes
201 were then incubated with 10 ml Qdot 625 Streptavidin conjugate solution for 1 hour at room

202 temperature before being washed 3 times as previously described, followed by a final wash in MilliQ
203 water for 5 min. The membranes were soaked in 100% methanol to make them transparent and then
204 visualised under a UV trans-illuminator.

205 **Statistical Analysis**

206 Statistical analysis was carried out using SPSS V.16 (IBM, USA) and Microsoft Excel (Microsoft
207 corp. USA). Densitometry analysis was carried out using ImageJ software (Maryland, USA). All
208 protein bands were quantified and then normalised with respect to non-treated samples. The one-
209 sample Kolmogorov-Smirnov test was performed to determine whether the data for each gene/protein
210 were normally distributed. Where the data were normally distributed, significant differences in
211 gene/protein expression levels between fresh and chilled embryos at the same time point were
212 calculated using a t-test and the one way ANOVA was carried out followed by Tukey's post hoc tests
213 to identify changes in gene/protein expression levels between treatments. Where data were not
214 normally distributed after logarithmic transformation, the Mann-Whitney U test was used instead. All
215 gene and protein expression data were presented as mean \pm SEM and *p* values of less than 0.05 were
216 considered significant.

217 **3. Results**

218 **Experiment 1: The effect of 18 h chilling on hatching rate in zebrafish embryos in the** 219 **presence of sucrose and MeOH**

220 Significant increases ($p < 0.05$, Tukey's post hoc test) in hatching rates were observed in the embryos
221 that were chilled with 0.5 and 1 M MeOH + 0.1 M sucrose mixtures ($45 \pm 10\%$ and $56 \pm 5\%$) when
222 compared to embryos that had been chilled in different MeOH concentrations with 0.05 M sucrose [1
223 M MeOH + 0.05 sucrose ($15 \pm 5\%$), 0.5 M MeOH + 0.05 sucrose ($20 \pm 5\%$), 0.2 M MeOH + 0.05
224 sucrose ($10 \pm 3\%$) and 0.2 M MeOH + 0.1 M sucrose ($20 \pm 4\%$)] (Fig 1). No significant differences in
225 hatching rates were observed among embryos treated in 0.05 M sucrose with different concentrations
226 of MeOH.

227 **Experiment 2: The effect of 18 h chilling on *sox* gene expression in zebrafish embryos**

228 In non-chilled control embryos after 18 h at $27 \pm 1^\circ\text{C}$, *sox2* (Fig 2a) gene expression increased
229 significantly ($p < 0.05$, Tukey's post hoc test) when compared to time zero (0 h). However in the
230 embryos that were chilled at 0°C for 18 h without cryoprotectant, *sox2* gene expression was
231 significantly lower than non-chilled controls (Fig 2). No significant differences were observed
232 between non chilled embryos and those that had been chilled for 18 h in the cryoprotectant mixture
233 containing 1 M MeOH and 0.1 M sucrose. *Sox3* (Fig 2b) gene expression decreased significantly ($p <$
234 0.05 , Tukey's Post hoc test with log transformation)- after 18 h of development at RT and no
235 significant differences were observed in chilled embryos with or without cryoprotectant when
236 compared to non-chilled 18 h controls. A significant decrease in *sox19a* expression was also observed
237 in 18 h non chilled control embryos when compared to 0 h controls (Fig 2c). However, embryos that
238 had been chilled for 18 h in cryoprotectant mixture containing 1 M MeOH and 0.1 M sucrose had
239 significantly increased *sox19a* expression compared to the non chilled controls.

240 **Experiment 3: The effect of 18 h chilling and warming on *sox* gene expression in**
241 **zebrafish embryos**

242 In control embryos, gene expression of *sox2* remained stable and *sox3* and *sox19a* (Fig 3) gradually
243 decreased throughout development from 50% epiboly to hatching stage ($p < 0.05$). In the embryos that
244 had been chilled with 1 M MeOH + 0.1 M sucrose for 18 h and then warmed before being cultured to
245 the hatching stage, *sox2* (Fig 3a) and *sox19a* (Fig 3c) gene expression increased just after the chilling
246 period and again increased at the heartbeat stage before levelling up with non-chilled control embryos
247 at the hatching stage. The opposite patterns were observed for *sox3* (Fig 3b) as gene expression
248 decreased significantly ($p < 0.05$, Mann-Whitney U test) when compared to controls at 20 somites
249 stage and recovered at the heartbeat stage before decreasing significantly again at the hatching stage.

250 **Experiment 4: The effect of 18 h chilling and warming on *sox2* and *sox3* protein**
251 **expression in zebrafish embryos**

252 The effect of 18 h chilling on *sox2* and *sox3* protein expression in 50% embryos chilled with or
253 without 1 M MeOH + 0.1 M sucrose is shown in Fig 4. Protein expression profile is shown in Fig 4(a)
254 along with internal control β actin. Based on these results, densitometry was performed using ImageJ
255 software and data are presented in Fig 4(b). *Sox2* protein expression increased significantly ($p < 0.05$)
256 from 0 h to 18 h in control non chilled embryos. Embryos chilled without cryoprotectants
257 demonstrated significantly decreased *sox2* levels when compared to non-chilled 18 h controls ($p <$
258 0.01). However, embryos that had been chilled with 1 M MeOH + 0.1 M sucrose demonstrated no
259 significant changes in *sox2* protein expression when compared to 18 h non chilled embryos. *Sox3*
260 protein expression increased significantly in non-chilled 18 h embryos compare to 0 h. No significant
261 differences in *sox3* protein expression were observed in embryos that had been chilled with/without
262 cryoprotectant mixture compare to non-chilled 18 h control embryos.

263 Equivalent data for these embryos following culture to the hatching stage is shown in Fig 5. *Sox2*
264 protein expression was stable throughout the culture period and no significant differences were
265 observed between non-chilled control embryos and chilled embryos either with/without
266 cryoprotectants. *Sox3* protein expression increased significantly from 0 h (50% epiboly) to the
267 hatching stages in non chilled embryos, chilled embryos with or without cryoprotectant.

268 **4. Discussion**

269 Chilled storage is an important alternative to cryopreservation for fish embryos in aquaculture to
270 synchronize the development of embryos derived from different spawning dates or to delay the
271 development for extended periods of time. Maddock² demonstrated that in the brown trout (*Salmo*
272 *trutta*), embryo development can be delayed for up to 4 months at 1.4°C. Studies in the vendace
273 (*Coregonus albula*) showed that hatching of embryos can be delayed for several weeks by cooling
274 them at 1 to 2 °C in order to synchronize mass hatching for lake stocking²³. In the present study,
275 experiments were carried out in order to optimise the chilled storage protocol for zebrafish embryos

276 for 18 h at 0°C. Different mixtures of cryoprotectants were used in the chilling medium. Once embryo
277 hatching rates were optimised for 18 h chilling at 0°C, further studies on the effect of 18 h chilling in
278 the presence of cryoprotectant mixture on the gene and protein expressions were carried out. This
279 study was necessary as it has been shown that short term (3 h) chilling of embryos at 0°C does alter
280 the patterns of gene and protein expression⁸. The chilling conditions applied in the present studies
281 have practical applications in fish embryo handling in aquaculture e.g. embryo transportation between
282 fish farms in genetic improvement programs. Storage of embryos at 0°C for prolonged periods of time
283 slow down embryo development significantly therefore providing an alternative method for assessing
284 early stage embryos.

285 **Studies on the effect of 18 h chilling on hatching rate in zebrafish embryos in the** 286 **presence of sucrose and MeOH mixture**

287 Embryos (50% epiboly) were chilled at 0°C for 18 h with different concentrations of MeOH (0.2, 0.5
288 and 1 M) in combination of sucrose (0.05 or 0.1M). It was observed that hatching rates increased (56
289 ±5% and 45 ± 10%) significantly in embryos that had been chilled with 1 M or 0.5 M MeOH in 0.1 M
290 sucrose when compare to those chilled without cryoprotectants. Methanol has been widely used as a
291 cryoprotectant in zebrafish embryo cryopreservation and chilling sensitivity studies^{3, 19, 20, 24-27}. In our
292 previous study²⁸, no significant improvement compared to non-chilled controls (was observed in
293 embryos that were chilled for 18 h in 1 M MeOH) and embryo hatching rate was as low as 5% after
294 chilling at 0°C. It is clear from the present study that 1 M MeOH along with sucrose (0.1 M)
295 supplementation resulted in higher hatching rates than obtained when methanol alone was used
296 during longer term chilling of embryos for up to 18 h at 0°C. Zhang and Rawson³ obtained an 88.4%
297 hatching rate for heartbeat stage zebrafish embryos that had been chilled at 0°C for 18 h in 1 M
298 MeOH+0.1 M sucrose and the hatching rate decreased to 81% as the chilling period increased to 24
299 h. In the present study, a 56 ± 5% hatching rate was obtained for 50% epiboly stage embryos under
300 similar conditions. Decreased hatching rates in 50% epiboly embryos compared to the heartbeat stage
301 could be due to the fact that early staged embryos are more sensitive to chilling than late stage

302 embryos and chilling sensitivity decreases with development of embryonic stages³. Chilling
303 sensitivity in early stage zebrafish embryos is largely associated with large amounts of intraembryonic
304 lipids²⁴. Lipids are the second most abundant component of fish eggs after protein and account for up
305 to 52% of the dry weight of fish eggs³. As the stages progress, yolk is consumed and reduced which
306 makes later staged embryos less prone to chilling. Studies in medaka embryos⁶ (12 h hpf – early
307 gastrulation stage which is similar to 50% epiboly in zebrafish) also showed a 3-6 % increase in
308 hatching rates of embryos chilled up to 72 h at 0°C in methanol (3 M) supplemented with sucrose (0.5
309 M) when compared to those obtained from embryos chilled without sucrose. Addition of sucrose in
310 methanol also increased the survival of mrigal (*Cirrhinus mrigala*) embryos from 0% to 25% for tail-
311 bud stage embryos at 4°C for 12 h²⁹. This indicated the beneficial effect of sucrose when used in
312 combination with MeOH in protecting embryos from chilling injuries. The protective effect of sucrose
313 may be related to the moderate level of dehydration of embryos in the presence of sucrose which
314 might help in protecting the cell membrane from chilling injury⁴. The mechanisms of sugars such as
315 trehalose (which is similar to sucrose – both are disaccharides) in protecting cells from injuries at low
316 temperatures have been proposed by a number of studies. Trehalose acts as a compatible solute and is
317 an excellent protector of membrane and proteins, it protects membranes during dehydration by
318 hydrogen bonding to the phospholipid head group³⁰. This interaction increases head-group spacing,
319 hence lowering the transition temperature of the phospholipids³¹. Unlike methanol, which penetrates
320 into the cell membrane and protects cells intracellularly, sucrose does not penetrate the cell membrane
321 and functions at the extracellular surface of the cells. At this site, the disaccharides increase the
322 osmolarity of medium, thereby preventing fewer water molecules to contact the cell exterior. This
323 process reduces the effect of low temperature on cells and stabilises cell membranes and proteins³².
324 However, a high concentration of sucrose (1 M) alone caused 100% mortality of early gastrula stage
325 common carp embryos after 12 h storage at 0°C³³. This may be a result of severe dehydration of the
326 embryos caused by high osmolarity of the sucrose solution.

327 **Studies on the effect of 18 h chilling on *sox* gene and protein expression in zebrafish**
328 **embryos**

329 Previously, it was observed that 1 M MeOH supplemented with 0.1 M sucrose provided improved
330 hatching rates when embryos were chilled for 18 h at 0°C. The present studies were carried out to
331 investigate whether the use of this cryoprotectant mixture had any effect on *sox* gene and protein
332 expression in embryos that had been chilled for 18 h at 0°C. No significant differences were observed
333 in *sox3* gene expression (Fig 2b) and protein expression (Fig 4) between 18 h non-chilled control
334 embryos and chilled embryos with or without cryoprotectant. However, significant decreases were
335 observed in *sox2* gene (Fig 2a) and protein expression (Fig 4) in 18 h chilled embryos without
336 cryoprotectant when compared to non-chilled 18h control. No significant differences were observed in
337 the 18 h chilled embryos with 1 M MeOH when compared with 18 h RT control. Previous hatching
338 rate results showed improved hatching rate in the embryos that had been chilled for 18 h at 0°C with 1
339 M MeOH+0.1 M sucrose cryoprotectant mixture compared to other combination of MeOH and
340 sucrose. Chilling for prolonged periods can cause indirect chilling injury³⁴. Enzymes are affected by
341 indirect chilling injury at low temperature which may have downstream effects on their function and
342 the metabolic pathways. They contribute to the disorder of metabolic and enzymatic processes can be
343 detrimental in fast developing embryos like *Drosophilla* and such injury increases rapidly at lower
344 temperatures due to loss of co-ordination with reducing temperature³⁵. Moreover, reduced temperature
345 may also have adverse effects on the cytoskeleton system i.e. depolymerisation of microtubules^{36, 37}
346 which could result in irreversible disruption of cellular process like cell division in oocytes^{38, 39}.
347 Damage to the lamina (a part of nuclear envelope) has been reported to affect gene expression as
348 proteins within these also function as structural nuclear protein and are involved in regulation of gene
349 expression⁴⁰. Laminae have also been found to be associated with heterochromatin, at sites of DNA
350 replication, RNA processing, replication protein and RNA polymerases. Any changes in lamina due to
351 chilling injury may have affected such processes and could result in alteration in mRNA transcription
352 and subsequent translation. If such damage occurs, cells would appear morphologically normal
353 following warming, however, future development of the cells could be compromised⁴⁰. Changes in

354 gene expression also affect the protein expression. In this study, it was observed that decreased *sox2*
355 gene transcripts after 18 h chilling coincided with decreased *sox2* protein expression. This change in
356 protein expression could be mainly due to changes in mRNA transcript, which is needed to initiate
357 protein synthesis. Changes in transcription and translation levels also affect phenotypical changes in
358 embryo development as hatching rates were decreased significantly. Gene and protein expression of
359 *sox2* did not show any decrease in 18 h chilled embryos in 1 M MeOH + 0.1 M sucrose and remained
360 stable compared to 18 h non chilled control. Relatively stable gene and protein expression is reflected
361 in high hatching rates in the embryos.

362 **Studies on the effect of 18 h chilling and warming on *sox* gene and protein expression in** 363 **zebrafish embryos**

364 In the previous section, it was discussed that 1 M methanol plus 0.1 M sucrose protected gene and
365 protein expression of the embryos following chilling for 18 h. When chilled embryos were
366 subsequently cultured to the hatching stages at $27 \pm 1^\circ\text{C}$, *sox2* and *sox19a* gene expression was
367 increased significantly at the heartbeat stage and just after 18 h chilling respectively, when compared
368 to non-chilled controls before decreasing to non-chilled control levels by the hatching stage. However,
369 no significant differences were observed at the protein level for *sox2*. No significant differences was
370 observed in *sox3* protein expression in the hatched embryos chilled for 18 h in 1 M MeOH +0.1 M
371 sucrose compare to non-chilled 18 h controls. Results obtained from this study supported by higher
372 hatching rate in the embryo that had been chilled for 18 h in cryoprotectant mixture and cultured to
373 hatching stage, despite the changes in *sox3* gene expression in hatched embryos. Sox genes have
374 capability to bind with other transcription factor proteins to activate or repress specific target genes⁴¹,
375 ⁴². A study in early blastula to gastrula stage zebrafish embryos by a quadruple knockdown technique
376 demonstrated that B1 *sox* genes (*sox2/sox3/sox19a/sox19b*) are highly redundant and their encoding
377 proteins are functionally interchangeable in early zebrafish embryogenesis ⁴³. Therefore changes in
378 *sox3* gene expression could have been compensated by the increased expression of *sox2* and *sox19a*
379 genes observed here. Stable *sox3* protein expression in hatched embryos after they were chilled for 18
380 h in cryoprotectant mixture when compare to non-chilled control could be due to the post

381 transcriptional repair mechanism which involves the post transcription and translation modification to
382 repair the loss of *sox3* mRNA transcript due to chilling for 18 h. Similar mechanism explained in
383 parasite *Giarida* after chilling for 20 min on ice demonstrated loss of *hsp90* transcript which was later
384 repaired by the post transcriptional repair mechanism, mRNA *trans*-splicing⁴⁴.

385 To summarise, a 18 h chilled storage protocol for early stage zebrafish embryos was developed that
386 did not significantly compromise *sox* gene expression. 1 M MeOH + 0.1 M sucrose cryoprotectant
387 mixture was found to improve embryo hatching rates following chilling for 18 h at 0°C compared to
388 embryos that had been chilled in 1 M MeOH + 0.05M sucrose or in MeOH alone. This indicated the
389 beneficial effect of sucrose when used in combination with MeOH in preventing embryos from
390 chilling injuries and disruption of the embryonic transcriptional regulators. However, this work was
391 limited to three genes. More work is therefore needed with a larger number of gene sets to have
392 overall picture of embryonic development using this protocol. Another area of study would be to
393 assess changes in gene and/or protein expression in specific areas within embryos to check for any
394 localized changes in transcriptional response.

395

396 **Acknowledgement:**

397 Funding support for this programme of research was provided by the strategic research fund of the
398 Institute of Biomedical and Environmental Science and Technology, University of Bedfordshire,
399 Luton, UK.

400 **Conflict of Interest:** None declared.

Figure and table legends

Table 1

Information on gene name, accession ID and primer sequences including annealing temperature and product size.

Figure 1: Effect of chilling on hatching rate in 50% epiboly stage of zebrafish embryos

Embryos were chilled for 18 h in different combinations of MeOH and sucrose followed by culturing at $27\pm 1^\circ\text{C}$ for up to three days and until they hatched. Bars represent hatching rates of zebrafish embryos after chilling at 0°C for 18 h in different concentrations of MeOH (0.2, 0.5 and 1 M) plus sucrose (0.05 – 1 M), followed by incubation at $27\pm 1^\circ\text{C}$ for three days. Error bars represent the standard error of the mean (SEM). Different letters show significant differences ($p < 0.05$) between different chilling treatments (n=9).

Figure 2: Effect of chilling in the presence of MeOH and sucrose on *sox* gene expression in 50% epiboly stage of zebrafish embryos

Gene expression profile for *sox2* (a), *sox3* (b) and *sox19a* (c) for embryos that had been chilled for up to 18 h at $^\circ\text{C}$ with or without MeOH + sucrose. Non chilled control embryos were kept at $27\pm 1^\circ\text{C}$. Gene expressions were assessed by reverse transcriptase qPCR. For each time point, 5 embryos were collected in triplicate and each experiment was repeated three times. Points represent the mean expression level relative to the non chilled controls and error bars represent standard errors of the mean (SEM). Different letters show significant differences ($p < 0.05$) between different conditions of chilling within the same developmental gene (n=9).

Figure 3: Effect of chilling in the presence of MeOH + sucrose and warming on *sox* gene expression in 50% epiboly stages of zebrafish embryos:

Gene expression profile for *sox2* (a), *sox3* (b) and *sox19a* (c) for embryos chilled up to 18 h at $^\circ\text{C}$ with or without MeOH + sucrose followed by warming at $27\pm 1^\circ\text{C}$ up to hatching stage, assessed by reverse

transcriptase qPCR. Non chilled control embryos were kept at $27\pm 1^{\circ}\text{C}$. For each time point, 5 embryos were collected in triplicate and each experiment was repeated three times. Points represent the mean expression level relative to 0 h time point and error bars represent standard errors of the mean (SEM). Asterisk (*) shows significant differences ($p < 0.05$) in gene expression between control treatment within the same developmental gene (n=9).

Figure 4: Effect of 18 h chilling with or without 1 M MeOH and 0.1 M sucrose mixture on *sox2* and *sox3* protein expression in 50% epiboly stage zebrafish embryos

Protein expression profiles of *sox2* and *sox3* for embryos chilled for 18 h at 0°C were assessed by western blot. For each time point, 75 embryos were collected in triplicate and each experiment was repeated three times. Points represent the mean expression level relative to the control at time zero and error bars represent standard errors of the mean (SEM). Different letters show significant differences ($p < 0.05$) between different chilling treatments of zebrafish embryos within developmental stages (n=9)

Figure 5: Effect of 18 h chilling with or without 1 M MeOH and 0.1 M sucrose mixture and warming on *sox2* and *sox3* protein expression in hatching stage zebrafish embryos

Protein expression profiles of *sox2* and *sox3* for embryos chilled and warmed until hatching stage for 18 h at 0°C were assessed by western blot. For each time point, 75 embryos were collected in triplicate and each experiment was repeated three times. Points represent the mean expression level relative to the control at time 0 and error bars represent standard errors of the mean (SEM). Different letters show significant differences ($p < 0.05$) between different chilling treatments of zebrafish embryos within developmental stages (n=9)
