## ABSTRACT

This poster describes an original approach to creating static and dynamic sculptures in a cubist style. We propose a novel method for faceting and local distortion thus adding cubist features and generating time-variant sculptural shapes. We introduce the concept of a 4D cubist camera for blending multiple projections from 4D space-time to 3D space. We describe a practical pipeline embracing all the main phases of production of static and dynamic cubist shapes. The proposed techniques are implemented and experimental results are presented.

## 1 INTRODUCTION

Dynamic sculptures created with help of computer-aided design and animation tools and related to a proper artistic style and tradition within a particular artistic movement are surprisingly rare. Of

course, there are well-established methods and tools allowing for modelling, rendering and animation of an almost infinite variety of shapes. There are also some powerful design tools for sculpturing static shapes [Séquin 2005]. However, creating dynamic art shapes are mostly concerned with traditional engineering and manufacturing practices. In this project we consider an original approach to creating artistic shapes related to the cubism movement.

This project has also served as inspiration for some original theoretical concepts integrating modelling and animation in the context of multidimensional conceptual space. There are parallels between cubism and 4D space, nD space and non-Euclidian geometries [Robbin 2006] which have influenced the project.

## 2 OUR APPROACH

### 2.1 Overview

Cubist painters moved away from traditional methods of projecting a 3D scene onto a 2D canvas, instead experimenting with using multiple viewpoints in a single composition. We propose to look at the theme of reducing the dimensionality of a scene through the new concept of a 4D cubist camera, which, by analogy with the well-established 3D cubist camera [Glassner 2004], is projecting two or more instances of a time-variant shape from 4D space-time to 3D space with possible preliminary blending between these instances. Whilst the 3D cubist camera [Arpa et al. 2012] deals with just rendering, this novel 4D cubist camera realises integration of modelling and animation phases through blending (i.e. compressing) a few frames generated on the basis of a faceted model with attached time-variant transformations into one thus producing cubist effect.

We propose a general shape model and develop algorithms to implement all the distinctive features of cubist sculptures. Then, combine the tools into a single system with artist's interactive or procedural control. We will use a hybrid representation combining polygonal meshes with signed distance fields (SDFs). We will cover

Figure 2: Cubification and animation production pipeline.

all the steps through the full production pipeline from data acquisition, to shape modelling, animation, rendering and 3D printing (Fig. 2).

### 2.2 Shape Faceting

Figure 3: Steps of faceting the given sculpture from left to right: initial shape (scanned model, Three D Scans); corresponding octree; associated primitive solids; rotated and scaled facets combined with manipulated initial mesh.

Cubification of an artistic 3D shape is based on subdivision into solid pieces (facets). Octree-based subdivision is used as it provides a loose form of feature sensitivity. Shapes and transformations are associated with each of the leaf nodes in the resulting tree structure. Each of the shapes are then intersected with the original shape and transformed using their associated transformation. The resulting facets are then combined with the initial mesh to produce the final result (Fig. 3). Facet transformations can be animated by the artist to produce dynamic sculptures.

### 2.3 4D Cubist Camera

Figure 4: Space-time blending applied to non-adjacent instances of a rotating and oscillating cube.

We employ space-time blending [Pasko et al. 2004] for combining (or compressing) several shape instances (frames) into a single shape. Note that in this process animation is considered as modelling in 4D with projections to 3D. Space-time blending was used

to generate motion trails to follow the facets produced by the octree method described earlier. To achieve this, the blend is performed between non-adjacent shape instances (frames)  $t$  and  $t - n$ . This allows for the effects of the surrounding frames of an animation to influence the current frame being viewed, producing a cubist-type projection of 4D space-time onto 3D space (see fig. 1 and fig. 4).

### 2.4 Implementation and Experiments

Houdini was a natural choice as the host application for the tools developed in this work. The implemented techniques rely heavily on the use of sparse volumes (discretised SDFs) from the OpenVDB library developed by DreamWorks Animation.

Figure 5: Left to right: 3D printed results showing faceted statue; a faceted mug from 3D scan data; a faceted articulated human rendered with a 3D cubist camera.

## 3 CONCLUSION

We have proposed an original approach to adaptive cubification of existing sculptures including faceting and local distortions. A new concept of a 4D cubist camera as a projection method from 4D to 3D was introduced. A pipeline embracing all the phases of artistic production has been realised. Some artefacts produced during this project can be seen in Fig. 5, the supplementary video and images.
