ABSTRACT

- 1
2
3 26
4
5 27
6
7
8 28 1. Mahseer (*Tor* spp.) are flagship fishes in South Asian rivers. Their populations are
9
10 29 threatened through poaching and habitat disturbance, yet they are highly prized game
11
12 30 fishes due to their large size, appearance and sporting qualities. The international
13
14 31 recreational angling community has been frequently cited as playing a vital role in
15
16 32 conserving these fishes while also providing economic benefit to poor rural communities.
17
18
19 33
20
21 34 2. Due to a lack of scientific data and the considerable challenges associated with monitoring
22
23 35 fish populations in large monsoonal rivers, efforts to determine the long-term trends in
24
25 36 their populations has focused on sport-fishing catch records. Here, catch data collected
26
27 37 between 1998 and 2012 from Galibore, a former fishing camp on the River Cauvery,
28
29 38 Karnataka, India, were analysed to determine the catch per unit effort (CPUE - by number
30
31 39 and weight) as an indicator of relative fish abundance, along with the size structure of
32
33 40 catches. This fishery operated a mandatory catch-and-release (C&R) policy, and provided
34
35 41 the fish community with protection from illegal fishing.
36
37
38 42
39
40 43 3. Between 1998 and 2012, 23,620 hours fishing effort were applied to catch and release
41
42 44 6,161 mahseer, ranging in size from 1 to 104 lbs (0.45 – 46.8 kg) in weight. Across the
43
44 45 period, CPUE in number increased significantly over time with a concomitant decrease in
45
46 46 CPUE by weight, revealing strong recruitment in the population and a shift in population
47
48 47 size structure. This suggests a strong response to the C&R policy and the reduction in
49
50 48 illegal fishing, indicating that conservation strategies focusing on the beneficial and
51
52 49 negative aspects of exploitation can be successful in achieving positive outcomes.
53
54
55
56 50
57
58
59
60

1
2
3 51 4. These outputs from angler catch data provide insights into the mahseer population that
4
5 52 were impossible to collect by any alternative method. They provide the most
6
7 53 comprehensive analysis of a long-term dataset specific to any of the mahseer species
8
9
10 54 across their entire geographical range and demonstrate the value of organised angling as a
11
12 55 conservation-monitoring tool to enhance biological data, and inform conservation and
13
14 56 fishery management actions.

INTRODUCTION

Freshwater fishes comprise one of the most threatened taxa on earth (Cooke *et al.*, 2012; Carrizo *et al.*, 2013; Reid *et al.*, 2013), with the extinction of approximately 60 species since 1500 and a further 1679 currently threatened with extinction (Carrizo *et al.*, 2013). Despite that, conservation attention on these fishes is limited, mostly attributable to issues relating to knowledge gaps on key life history traits, population and habitat requirements, and geographical distributions, all of which are crucial for developing and implementing effective conservation actions (Cooke *et al.*, 2012). Moreover, these knowledge gaps are increasing as taxonomists continue to discover and describe new species of freshwater fishes, many of them from habitats that are already facing high levels of anthropogenic disturbance.

Collection of inland fisheries data, particularly in biodiversity rich, tropical countries, can be extremely challenging as many of the sites are located in remote areas and extreme habitats which are often inaccessible for research, and where a lack of political will further limits both financial capacity and human resource (Mahon, 1997; Arce-Ibbara and Charles, 2008). Improving knowledge and understanding of freshwater fish and inland fisheries in these countries and regions therefore needs to consider the use of alternative, cost-effective approaches (Bene *et al.*, 2009; Raghavan *et al.*, 2011; de Graaf *et al.*, in press). Due to the often threatened status of the fish species concerned, allied with legislation that seeks to protect these species (even if management strategies are yet to be developed due to the knowledge gaps), these alternative approaches should also be non-destructive and have a strong ethical basis.

1
2
3 90 Mahseer (*Tor* spp; Cypriniformes: Cyprinidae) are large-bodied freshwater fishes that are
4
5 91 endemic to the monsoonal rivers of Asia. They are popular throughout their range as flagship
6
7 92 species of considerable economic, recreational and conservation interest (Siraj, 2007; Nguyen
8
9 93 et al., 2008; Singh and Sharma, 1998). Of the 18 valid species of *Tor* mahseer (Eschmeyer,
10
11 94 2014; Kottelat, 2013), six species (*Tor ater*, *Tor khudree*, *Tor kulkarnii*, *Tor malabaricus*,
12
13
14 95 *Tor putitora* and *Tor yunnanensis*) are 'Endangered', one is 'Near Threatened', and six
15
16 96 species are 'Data Deficient' on the IUCN Red List (IUCN, 2013; www.iucnredlist.org). The
17
18 97 remaining five species have not been assessed for their conservation status. Despite this, data
19
20 98 on mahseer populations are severely limited, with even fundamental aspects such as
21
22 99 taxonomy, autecology, and population demographics being unknown for many species
23
24
25 100 Raghavan *et al.*, 2011; Pinder and Raghavan, 2013). For example, there are no population
26
27 101 estimates available for the endangered species *T. khudree* and *T. malabaricus* (Raghavan,
28
29 102 2011; Raghavan and Ali, 2011). Nevertheless, they are internationally recognised for their
30
31 103 large size, attractive appearance, and sporting qualities by recreational anglers; in India, they
32
33 104 are known as the 'King of aquatic systems' (Langer *et al.*, 2001; Dhillon, 2004) and comprise
34
35 105 one of the primary groups of fish targeted by recreational fishers (Cooke *et al.*, *in press*).
36
37 106 Indeed, the little information that is available on Indian mahseer populations has largely
38
39 107 originated from, or is related to, the recreational angling community (e.g. Thomas, 1873;
40
41 108 MacDonald, 1948; Trans World Fishing Team, 1984; Dhillon, 2004; Everard and Kataria,
42
43 109 2011; Pinder and Raghavan, 2013).
44
45
46
47
48

49 111 The recreational angling community offers a social group that positively supports fish
50
51 112 conservation (Arlinghaus, 2006) and recreational fishers have engaged in various activities
52
53 113 contributing to freshwater fish conservation such as monitoring, research, management,
54
55 114 advocacy, and education (Granek *et al.*, 2008; Cooke *et al.*, *in press*). For example, in India,
56
57
58
59
60

1
2
3 115 the recreational fishing sector has played an integral part in the conservation and management
4
5 116 of mahseers through such activities as the implementation of compulsory catch-and-release
6
7 117 (C&R), stock augmentation, stock protection and, in some cases, the maintenance of catch
8
9 118 log books (Everard and Kataria, 2011; Pinder and Raghavan, 2013; Cooke *et al.*, in press).
10
11 119 Nevertheless, despite recreational fishers and fishery managers having been previously
12
13 120 identified as a potentially valuable source of data, there are, to date, no previous efforts to
14
15 121 exploit these catch log-books. Consequently, in this study, catch log-book data from the
16
17 122 Galibore Fishing Camp on the River Cauvery were assessed over a 15 year period (1998 to
18
19 123 2012). In this period, the fishery management objectives were the release of all rod-caught
20
21 124 mahseers and the elimination of poaching throughout the controlled (~7km) length of river
22
23 125 through enforcement. The study objectives were thus to: (i) determine the temporal trends in
24
25 126 catch per unit effort (CPUE - by number and weight) of mahseer captured by recreational
26
27 127 fishers; (ii) assess the extent to which the size structure of the mahseer population has
28
29 128 changed over time and how this might be related to the fishery management objectives; and
30
31 129 (iii) assess the implications of the outputs in relation to recreational fishery exploitation and
32
33 130 species conservation.

132 MATERIALS AND METHODS

133
134 The Cauvery (basin area of 87900 km²) (De Silva *et al.*, 2007) is a major east flowing
135 river draining the Western Ghats, an exceptional area of freshwater biodiversity and
136 endemism in peninsular India (Molur *et al.*, 2011). The Cauvery and its tributaries comprise
137 one of the two (the other being the Himalayan Ganges) river systems where C&R angling for
138 the mahseer has been practiced since the colonial times (Thomas, 1873; Dhu, 1923;
139 MacDonald, 1948). Galibore Fishing Camp represents one of four former angling camps

1
2
3 140 situated on the River Cauvery encompassed by the Cauvery Wildlife Sanctuary (an IUCN
4
5 141 Category IV Protected Area) in the state of Karnataka, Southern India (Fig. 1). The Wildlife
6
7 142 Association of South India (WASI) came into existence in 1972 with a mandate 'to conserve
8
9 143 and preserve the wildlife of South India'. This Bangalore based Non-Governmental
10
11 144 Organization was instrumental in the early development of the C&R fishery which
12
13 145 encompassed the 7 km beat at Galibore and extended 22 km between Mutthatti and Mekedatu
14
15 146 (Fig. 1). Due to the recognised revenue potential of the fishery, in 1999, Galibore along with
16
17 147 two further camps (sited between Galibore and Shivasamudram Falls were developed into
18
19 148 semi-permanent eco-tourism establishments by the state government-owned Jungle Lodges
20
21 149 and Resorts (JLR). WASI's successful model of employing guards to man anti-poaching
22
23 150 camps was maintained and supported by both WASI and JLR at Galibore until 2012, when
24
25 151 the entire fishery was closed (see Pinder and Raghavan, 2013).
26
27
28
29

152

30
31
32 153 Despite current contention regarding the taxonomic identity of mahseer species present
33
34 154 within this section of the Cauvery, there exist two well defined morphs which are known as
35
36 155 blue finned mahseer and golden or hump-back mahseer. As works to resolve the exact
37
38 156 identity of these 'species' are underway, this paper refers only to the phenotypic descriptions
39
40 157 as 'blue-finned' and 'golden' mahseers so as to avoid risk of perpetuating erroneous
41
42 158 scientific names.
43
44
45

46 159 The fishing season for mahseer typically extends from November to March, with fishery
47
48 160 performance considered to peak, providing consistent sport quality (number and size of fish
49
50 161 caught) between January and March when river flows are at their lowest and angling can be
51
52 162 practised effectively.
53
54

163

1
2
3 164 Between mid-January and mid-March of 1998 to 2012, the mahseer fishery was subject to
4
5 165 regulated angling pressure (maximum 10 rods/day), practicing a very strict C&R policy.
6
7 166 Structured catch data collected during this period included daily records of individual angler
8
9 167 identity (name); hours fished (effort); number of fish caught; weight of individual fish (the
10
11 168 standard metric used by anglers was imperial lbs) and notes relating to mahseer phenotype.
12
13 169 With the exception of two years (1999 and 2000), a sub-sample of catch returns spanning
14
15 170 1998 – 2012 were available from the fishery manager and complemented by additional
16
17 171 returns retained by anglers over the same period. The resolution of the recovered data set is
18
19 172 summarised in Table 1.
20
21
22
23

24
25 174 While all larger mahseer (>10 lbs (>4.5 kg)) were typically weighed to the nearest pound
26
27 175 using spring loaded weighing scales, many weights of smaller individual fish were found to
28
29 176 be restricted to estimates. Furthermore, where an angler recorded a large number of fish
30
31 177 during a single (4 hour) fishing session, records were typically limited to the weight of the
32
33 178 largest fish with the remaining catch enumerated, e.g. *six fish to 18 lbs*. Following
34
35 179 consultation with the camp manager and a selection of the anglers, these data have been
36
37 180 standardised by recording one fish at 18 lbs with all other individuals recorded as weighing 5
38
39 181 lbs (5 lbs representing the threshold at which most anglers were considered to neither weigh
40
41 182 nor estimate the weight of their fish). Where the weight of the largest individual did not
42
43 183 exceed 5 lbs (either estimated or weighed), e.g. *nine fish to 5 lbs*, data were standardised by
44
45 184 applying a 50% weight reduction to the remaining eight fish for which weights were not
46
47 185 recorded. In this example the adjusted record would account for one fish of 5 lbs and eight
48
49 186 fish of 2.5 lbs. While the authors' acknowledge the inherent limitations of these standardised
50
51 187 data, the allocation of arbitrary weights (as guided by the local angling community) has
52
53
54
55
56
57
58
59
60

188 facilitated a valuable measure of the numbers of young fish recruiting to the population over
189 the course of the study period.

190
191 The initial step in the data analyses was to determine catch per unit by number and weight
192 for each year. These data were then analysed in linear mixed models where the final model
193 used angler identity as the random variable (to account in the model for differences in their
194 respective abilities, differences in fishing style etc., and in relation to their catches), year as
195 the independent variable and catch per unit effort (either in number or weight) as the
196 dependent variable. Outputs included estimated marginal means (i.e. mean adjusted CPUE by
197 year) and the significance of their differences between years according to pairwise
198 comparisons with Bonferroni adjustment for multiple comparisons. In addition, the mean
199 weights of fish captured per year were tested using ANOVA with Tukey's post-hoc tests. All
200 statistics were completed in SPSS v.21.0.

201 RESULTS

202
203 Annual median CPUE increased over the period, although the within-year variability of
204 the data was considerable (Fig. 2). The linear mixed models were significant for both catch
205 per unit effort by number ($F_{12,251} = 18.56$, $P < 0.01$) and weight ($F_{12,251} = 6.13$, $P < 0.01$), with
206 pairwise comparisons revealing significantly higher CPUE by number between 2010 and
207 2012 compared to the highest CPUE by number recorded in the early 2000s (2001; $P < 0.01$;
208 Fig. 3). There were, however, no significant differences in the mean adjusted catch per unit
209 effort by weight per year ($P > 0.05$; Fig. 3).

210
211 Over the study period, the mean weight of fish captured by anglers significantly decreased
212 (ANOVA, $F_{12,251} = 7.41$, $P < 0.01$), with Tukey's post-hoc tests revealing that the differences

1
2
3 213 between the highest mean weight recorded in the study, 1998, and subsequent years were
4
5 214 significant between 2007 and 2012 ($P < 0.05$; Fig. 4). The significant relationship between
6
7 215 CPUE by number and mean weight of fish revealed that as catch rates increased over time
8
9 216 they comprised of larger numbers of smaller fish (linear regression: $R^2 = 0.83$, $F_{1,11} = 22.93$,
10
11 217 $P < 0.01$; Fig. 4). Indeed, by categorising the captured fish into weight categories of 20 to 39
12
13 218 lbs, 40 to 59 lbs and > 60 lbs, it was apparent that the contribution of the largest fish to
14
15 219 catches significantly reduced between 2001 and 2012 (linear regression: $R^2 = 0.82$, $F_{1,10} =$
16
17 220 18.81 , $P < 0.01$; Fig. 5), but not in the smaller weight classes (21 to 40 lbs: linear regression:
18
19 221 $R^2 = 0.12$, $F_{1,10} = 1.21$, $P = 0.47$; 41 to 60 lbs: linear regression: $R^2 = 0.57$, $F_{1,10} = 0.57$, $P =$
20
21 222 0.47 ; Fig. 5).

28
29
30
31

226 DISCUSSION

32
33
34 227
35
36 228 The Indian Wildlife (Protection) Act 1972 (WPA) was enacted to provide much needed
37
38 229 legal protection to flora and fauna. Although this piece of legislation prohibits the hunting of
39
40 230 any 'wild animal' within areas set aside for protection (Protected Areas (PA)), the Act only
41
42 231 specifies amphibians, birds, mammals, and reptiles as constituting the term 'wild animal'
43
44 232 (Pinder and Raghavan, 2013). Lacking any formal amendment to recognise and include
45
46 233 freshwater fish, recently revised governmental interpretation of the Act has resulted in the
47
48 234 closure of the four former recreational mahseer fishing camps sited within the Cauvery
49
50 235 Wildlife Sanctuary. The phased closure of these camps between 2010 and 2012 has left fish
51
52 236 stocks previously afforded protection from poachers, once again vulnerable to the effects of
53
54 237 illegal and highly destructive harvest methods including the use of dynamite (Pinder and
55
56
57
58
59
60

1
2
3 238 Raghavan, 2013). Lacking any scientifically derived survey data, the daily catches recorded
4
5 239 by anglers at the Galibore Camp between 1998 and 2012 represent the only available data to
6
7 240 examine the temporal performance of the mahseer stock leading up to the implementation of
8
9 241 the angling ban and to explore any potential effects that the C&R fishery may have had on
10
11 242 the health of the population.
12

13
14 243

15
16 244 The outputs of the analyses of the catch data from the Galibore fishery revealed some
17
18 245 marked changes in catch composition over the study period, with increased numbers of
19
20 246 smaller fish appearing in catches that was allied with increased CPUE by number. This
21
22 247 successful use of recreational catch data to obtain insights into the mahseer population mirror
23
24 248 other examples of using recreational angler catch data as a tool to monitor freshwater fish
25
26 249 stocks and inform population management strategies (see Cowx, 1991; Granek *et al.*, 2008).

27
28 250 As a consequence of historic overexploitation, examples in many cases relate to species of
29
30 251 high economic value, either as food and/or sport fishes, which are now facing global and/or
31
32 252 localised population threats e.g. Atlantic salmon *Salmo salar* (Gee and Milner, 1980) and
33
34 253 white sturgeon *Acipenser transmontanus* (Inglis and Rosenau, 1994). In the case of
35
36 254 'Endangered' species which are endemic to developing countries (e.g. Eurasian taimen
37
38 255 *Hucho taimen* (Jensen *et al.*, 2009); mahseer *Tor* spp. (Pinder and Raghavan, 2013)),
39
40 256 resources available to monitor and manage fish populations are typically highly constrained,
41
42 257 thus limiting the development of effective management strategies which are urgently required
43
44 258 to foster a balance between exploitation and species conservation (Jensen *et al.*, 2009). Thus,
45
46 259 angler catch data can provide a very cost effective alternative in collating temporal and
47
48 260 spatial information on the fish stock that can provide information on long-term population
49
50 261 patterns and trends in that component of the stock that is being exploited (Cooke *et al.*, in
51
52 262 [press](#)).

1
2
3 263

4
5 264 While bait selection and angling method can be highly selective with respect to species and
6
7 265 sizes of fish captured (Mezzera and Largiadèr, 2001; Ussi-Heikkila *et al.*, 2008), such bias
8
9 266 were considered to be minimal here due to the very large mouth gape of even the smallest
10
11 267 mahseers. Despite some limited effort being applied by anglers to catch fish using artificial
12
13 268 lures, the primary method of capture was based on using large balls (~8cm diameter) of
14
15 269 cereal (Ragi, *Eleusine coracana*) derived paste as bait that appeared to randomly capture fish
16
17 270 of between 1 lb and 104 lbs (0.45 – 46.8 kg) in weight. This was thus likely to have reduced
18
19 271 the potential for variability in the data occurring through use of different methodologies. As
20
21 272 any inherent variance in individual angler ability in the dataset was also accounted for in the
22
23 273 analyses, the increased appearance of smaller fish in catches suggests this was due to their
24
25 274 greater availability to anglers. The data highlight an apparent threshold between 2007 and
26
27 275 2008, when CPUE by fish number and total weight demonstrated a marked increase. Given
28
29 276 that anecdotal evidence has suggested minimal stock augmentation in the river (S.
30
31
32 277 Chakrabarti, Wildlife Association of South India, pers. com.), the increased abundance of
33
34 278 smaller mahseer has been interpreted as occurring through elevated natural recruitment
35
36 279 success. The mechanisms responsible for the observed sudden increase in numbers are not yet
37
38 280 understood, but the strong year classes observed since 2008 could potentially be explained by
39
40 281 several years of more favourable environmental conditions (e.g. flows) being temporally
41
42 282 synchronised with key life history functions (e.g. spawning and early development).

43
44
45
46
47
48 283

49
50 284 When considering the abundance of fish recorded within weight categories, fish smaller
51
52 285 than 20lbs (<9 kg) were omitted from the analysis to guarantee the exclusion of all weights
53
54 286 derived by the standardised assumptions detailed within the methods section. Focusing only
55
56 287 on fish with individually angler assigned weights, it was apparent that the contribution of the
57
58
59
60

1
2
3 288 largest fish (greater than 60lbs (>27 kg)) to catches significantly reduced between 2001 and
4
5 289 2012 (Fig. 5). While this will have contributed to the overall decrease in mean weight over
6
7 290 the same period, it is important to note that these larger specimens were represented by a
8
9 291 distinct phenotype and referred to by anglers as ‘golden’ mahseer or the ambiguous ‘*Tor*
10
11 292 *mussullah*’ (Pinder and Raghavan, 2013; Cooke *et al.*, 2014; also see Knight *et al.*, 2013).
12
13
14 293 Establishing the true species identity and conservation status of these larger specimens lies
15
16 294 beyond the scope of the current study; however the notes associated with the current dataset
17
18 295 indicate the recent (post-2005) failure in recruitment of this golden phenotype. The resolution
19
20 296 of data collected by anglers between 1998 and 2012 therefore go beyond the provision of just
21
22 297 numbers and weights and might also contribute a better understanding of conservation
23
24 298 ecology in defining the temporal genetic composition of mahseer within this part of the River
25
26
27 299 Cauvery.

300

301 Environmental factors also require consideration in influencing catch statistics. Potential
302 drivers of catch success include river temperature (McMichael and Kaya, 1991), flow (North,
303 1980), and turbidity (Lehtonen *et al.*, 2009; Drenner *et al.*, 1997); all of which can vary in
304 response to natural climatic conditions and/or in response to river regulation and the
305 anthropogenic manipulation of flows from upstream dams and reservoirs (Barillier *et al.*,
306 1993; North and Hickley, 1977). Although environmental data are not available to
307 complement the current dataset, it is considered that due to the limited intra-annual
308 timeframes of focus (January – March), when weather and river conditions were typically
309 stable as it is outside of the monsoon season, that environmental factors were likely to have
310 played only a minimal role in influencing angling success over the study period.

311

1
2
3 312 In a recent review, Cooke *et al.* (in press) highlighted a global interest in targeting
4
5 313 endangered fish by recreational anglers and proposed a dichotomous decision tree of
6
7 314 indicators to inform whether the practice of C&R angling constitutes a conservation problem
8
9 315 or conservation action. The data recorded from the Galibore Camp between 1998 and 2012
10
11 316 clearly demonstrate a natural and indeed significant increase in mahseer population size.
12
13 317 However, qualifying the efficacy of the C&R management and stock protection programme
14
15 318 in driving the observed increase in fish biomass remains constrained by a lack comparative
16
17 319 empirical data from control sites, which were not afforded protection over the same period.
18
19 320 There are many references specifically documenting the long term efforts of the Cauvery
20
21 321 fishing camps and the role of the Wildlife Association of Southern India (WASI) in
22
23 322 protecting fish stocks by forcing poaching activities beyond the boundaries of the fishery
24
25 323 (Nair, 2010; Pinder and Raghavan, 2013; Pinder, 2013). Despite the largely anecdotal nature
26
27 324 of this information, the data presented within the present study, coupled with the fact that
28
29 325 recreational fishing interest for these highly prized fish has not since shifted beyond the
30
31 326 boundaries of the closed fishery, strengthens the evidence to support the effective
32
33 327 conservation benefits of the former management model practiced within the wildlife
34
35 328 sanctuary.
36
37
38
39
40
41
42

43 330 In light of the consistent fishery management practice applied across all four former camps
44
45 331 and throughout the entire controlled reach, it is considered that the Galibore catch data
46
47 332 provides representation of the performance of the mahseer population throughout the 22 km
48
49 333 between Mutthatti and Mekedatu Gorge (see Fig 1). Within the broader contexts of
50
51 334 catchment management (Nguyen *et al.*, 2008) and associated ecosystem services (Everard,
52
53 335 2013), the population growth and high biomass of mahseer shown to be present until 2012
54
55 336 may also have been significant at the catchment level. Indeed, in addition to the natural
56
57
58
59
60

1
2
3 337 dispersal behaviour typically exhibited by rheophilic cyprinids (Robinson *et al.*, 1998;
4
5 338 Reichard *et al.*, 2004), annual monsoon river flows are likely to have been highly effective in
6
7 339 delivering larvae and juveniles to the downstream reaches where annual augmentation of the
8
9
10 340 stock would have contributed to maintaining local populations and/or enhance the harvest
11
12 341 potential for sustenance fishers in downstream rural communities.
13

342

14
15
16 343 In summary, this structured catch dataset collected by recreational anglers visiting
17
18 344 Galibore between 1998 and 2012 represents the most comprehensive long term dataset
19
20 345 specific to any of the mahseers across their entire geographical range in Asia) and
21
22 346 demonstrates the value of organised angling as a monitoring tool to enhance biological data
23
24 347 and inform conservation and fishery management actions. Not only do these data demonstrate
25
26 348 the conservation benefits realised over a 15 year period, but also provide a unique baseline
27
28 349 against which the population response (either positive or negative) to the recent and radical
29
30 350 change in management policy, the closure of the catch and release fishery, could be qualified,
31
32 351 quantified, and considered against future conservation targets.
33

352

353

ACKNOWLEDGEMENTS

354

355 The authors wish to thank Sportquest Holidays Ltd, D. Plummer and M. Brown for the
356 provision of catch records. Maps and historical insight to the fishery were provided by S.
357 Chakrabarti and S. Raj. We are also grateful to A. Kanagavel for assisting in the production
358 of Figure 1. This research was supported by the Mahseer Trust.

2012	980			10	980

Figure captions

Figure 1. Location of the River Cauvery and the study area. Solid line represents the 7 km Galibore fishery. The dashed line represents the 22 km C&R fishery formerly controlled by WASI. Locations are coded: SF: Shivasamudram Falls, MU: Mutthattii, G: Galibore, MT: Mekedatu.

Figure 2. Box plot of year versus catch per unit effort (CPUE) of: *a*: number of fish per angler per hour, and *b*: weight (lbs) of fish per angler per hour, where the median, 25th and 75th percentile, and 10th and 90th percentile are displayed.

Figure 3: Mean adjusted catch per unit effort by number (*a*) and weight (*b*) by year, where the random effects of individual anglers in the data set have been accounted for in the model. * = Difference in catch per unit effort is significantly different from the highest value recorded in the early 2000s ($P < 0.01$). Error bars represent standard error.

Figure 4. *a*: Mean weight of fish captured per year, * Difference in mean weight significantly different from highest values in the early 2000s ($P < 0.01$). *b*: Relationship of mean adjusted catch per unit effort per year and the mean weight of fish captured in that year. In all cases, error bars represent standard error.

Figure 5. Plot of proportion of weight class of fish to total catch per unit effort by number according to year, where white boxes = 20 to 39 lbs, grey = 40 to 59 lbs, and black = > 60 lbs (1 lb = 0.45 kg).

For Peer Review

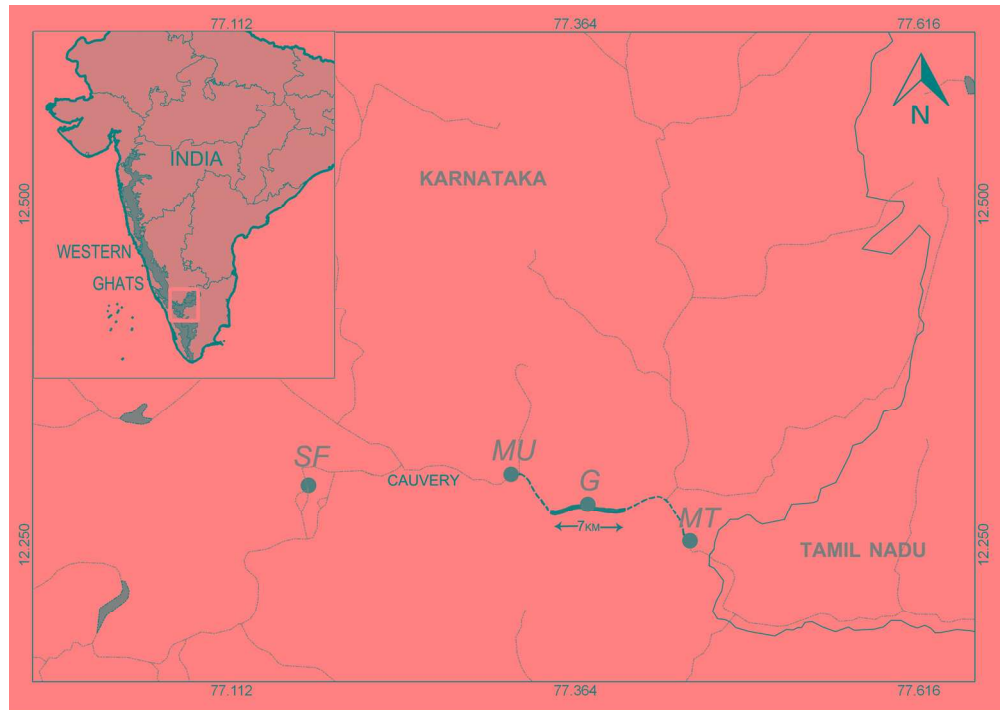

Figure 1. Location of the River Cauvery and the study area. Solid line represents the 7 km Galibore fishery. The dashed line represents the 22 km C&R fishery formerly controlled by WASI. Locations are coded: SF: Shivasamudram Falls, MU: Mutthattii, G: Galibore, MT: Mekedatu.
209x148mm (300 x 300 DPI)

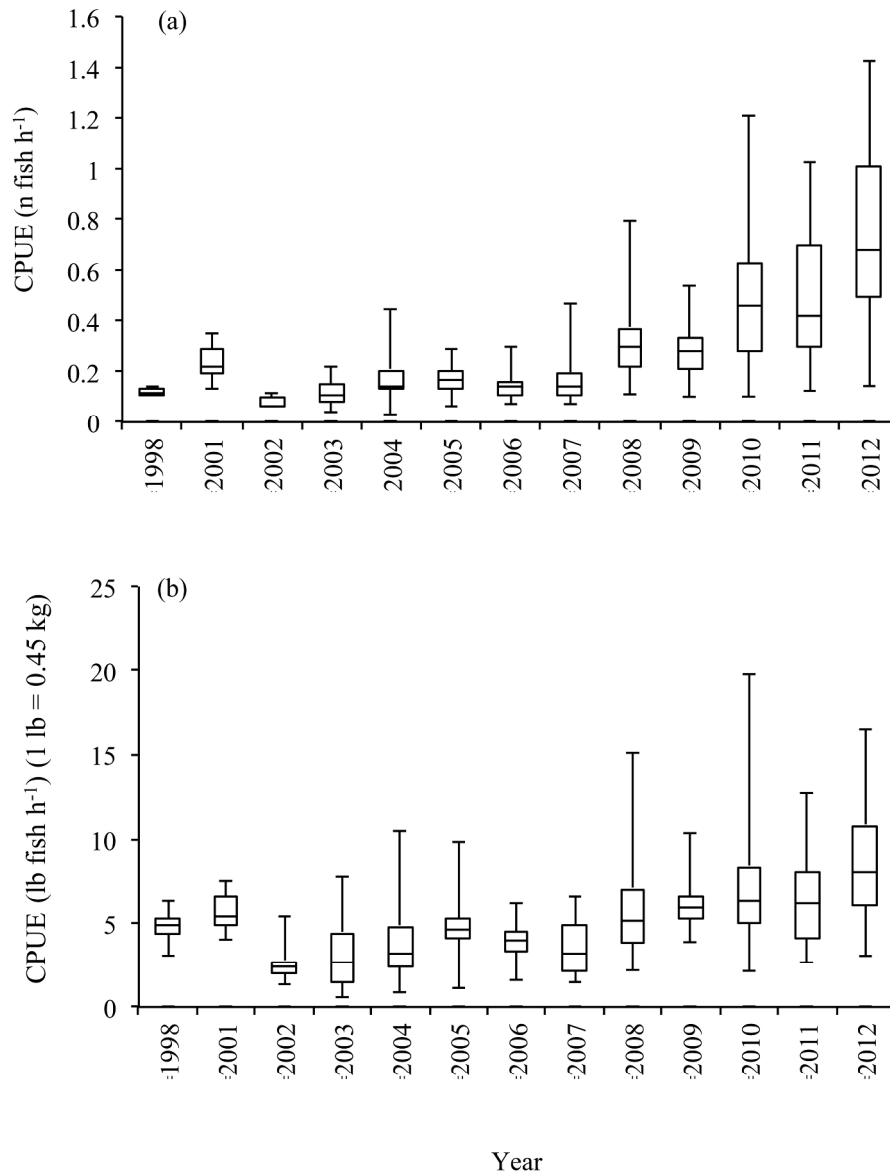

Figure 2. Box plot of year versus catch per unit effort (CPUE) of: a: number of fish per angler per hour, and b: weight (lbs) of fish per angler per hour, where the median, 25th and 75th percentile, and 10th and 90th percentile are displayed.
242x316mm (300 x 300 DPI)

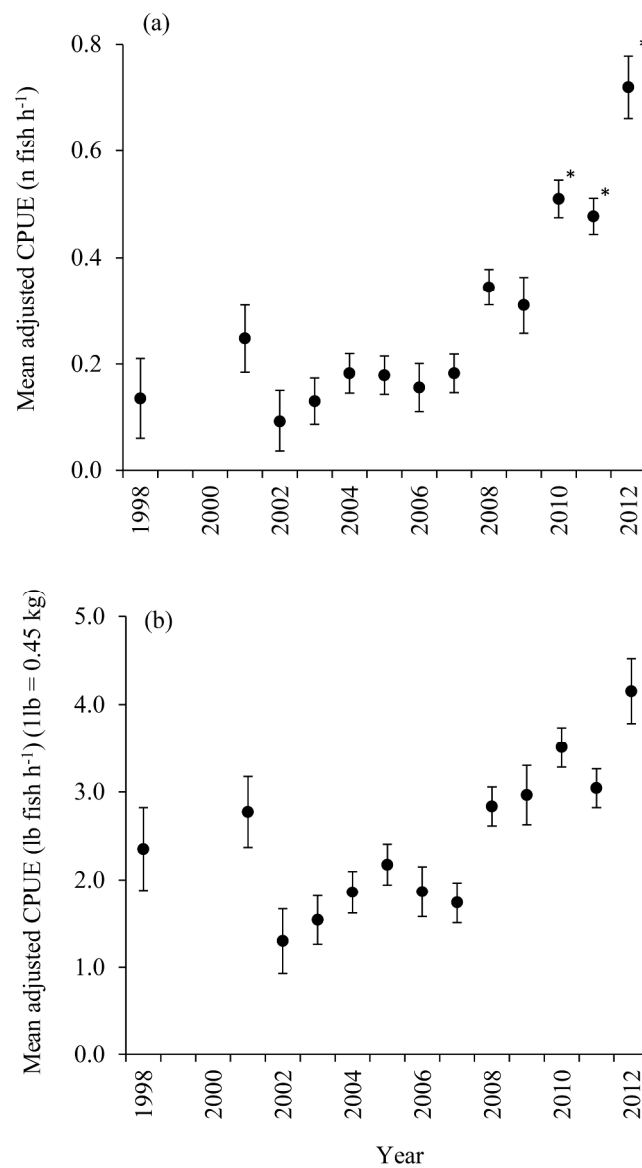

Figure 3: Mean adjusted catch per unit effort by number (a) and weight (b) by year, where the random effects of individual anglers in the data set have been accounted for in the model. * = Difference in catch per unit effort is significantly different from the highest value recorded in the early 2000s ($P < 0.01$). Error bars represent standard error.
205x349mm (300 x 300 DPI)

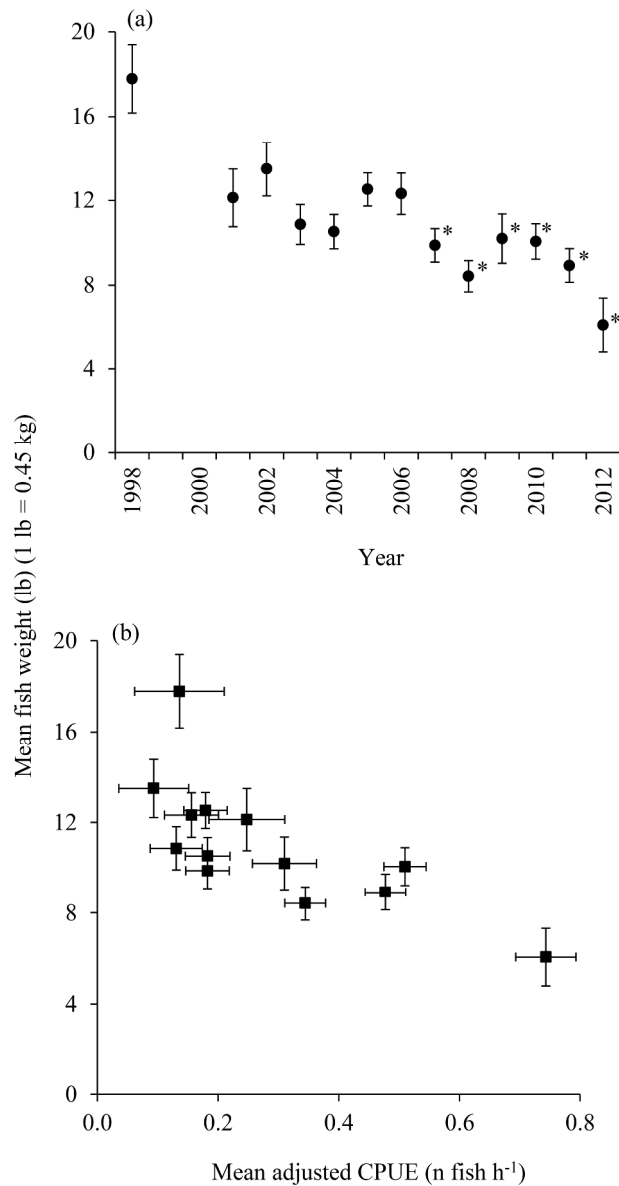

Figure 4. a: Mean weight of fish captured per year; * Difference in mean weight significantly different from highest values in the early 2000s ($P < 0.01$). b: Relationship of mean adjusted catch per unit effort per year and the mean weight of fish captured in that year. In all cases, error bars represent standard error.
212x404mm (300 x 300 DPI)

Figure 5. Plot of proportion of weight class of fish to total catch per unit effort by number according to year, where white boxes = 20 to 39 lbs, grey = 40 to 59 lbs, and black = > 60 lbs (1 lb = 0.45 kg).
149x114mm (300 x 300 DPI)
