Identifying key factors that encourage vegetable intake by young adults: using the Health Belief Model

Abstract

Purpose: Adequate vegetable consumption is fundamental to a healthy balanced diet; however, global compliance with recommendations is poor which is particularly important for young adults as they form food consumption habits. There is a growing interest in the circular economy of hospitality and sustainability of current dietary patterns in light of climate change and an expanding global population. The food value chain needs to be considered both vertically and horizontally where the R&D investment is optimised by being 'joined up' and not fragmentary; in addition, consumer trade-offs of health vs. for example sensory appeal are taken into consideration. The purpose of this study was to identify factors predicting acceptance of vegetable dishes by young adults and present a roadmap that can be used for dish development and healthful marketing.

Design: This study used the Health Belief Model as framework to investigate key factors that encourage vegetable intake by young adults using an online questionnaire sample of 444 enrolled in undergraduate programs at universities in Brazil.

Findings: Structural modelling showed that vegetable consumption frequency was positively influenced by Health concerns, Naturalness and Self-Efficacy (including cooking skills), whereas Sensory factors and Familiarity demonstrated a negative loading that might be related to unpleasantness.

Originality: Globally, there is a strong need to promote the consumption of vegetables as a public health policy priority but also to ameliorate barriers to action that could be facilitated by availability, dish development and healthful marketing in hospitality operations.

17 1. Introduction

18
19 Food plays a vital role with regard to health and sustainability in every society. However,
20
21 there is an urgency to transform it from being a cause of global challenges to one that
22
23 addresses them. The circular economy and its applicability to service-dominated industries,
24
25 such as hospitality, is barely considered and poorly researched (Sorin and Klitting, 2021).
26
27 Population health and the state of the planet rely on a food system that respects planetary
28
29 boundaries and prioritises societal health. A long-term strategy is therefore essential to create
30
31 healthy, enjoyable food for all, anchored within environmental parameters (Food, 2030,
32
33 2020). The expected 76% rise in the global appetite for meat and animal products by 2050
34
35 could increase greenhouse gases by 80% calling for action to mitigate climate change
36
37 induced by livestock (Food, 2030, 2020). The high resource footprint of producing animal-
38
39 derived food products is a key factor underpinning a growing interest amongst some
40
41 consumers for more 'sustainable diets' based upon alternative sources of protein (Bonnet *et*
42
43 *al.*, 2020) and a surging interest in the healthy functionality of food (Dias, 2012). There is a
44
45 large body of evidence surrounding the implications of the current global high levels of meat
46
47 consumption, with positive correlations between red meat intake and the risk of developing
48
49 type 2 diabetes (Wurtz *et al.*, 2021), cardiovascular disease (Zhong *et al.*, 2020), obesity and
50
51 some cancers (Lopez-Suarez, 2019). This emerging understanding of the negative
52
53 implications of meat consumption has led to policy makers becoming increasingly supportive
54
55
56
57
58
59
60

1
2
3 of a reduction for both health and environmental reasons with strategy advocating diets
4 higher in plant-based products (Willett *et al.*, 2019). Recently, COVID 19 has also focused
5 attention on well-being with 1 in 4 UK consumers cutting down on animal products during
6 the pandemic, and 40% of global consumers considering themselves ‘plant forward’ and
7 selecting ‘climate hero’ foods (WGSN, 2022).

8
9
10 There have been a number of studies investigating factors influencing general fruit and
11 vegetable consumption (e.g. Dubé *et al.*, 2019 and Gwozdz *et al.*, 2020) but limited empirical
12 research on vegetables alone especially within hospitality. Riverola *et al.* (2022) conducted a
13 qualitative study on building a greener dining scene and Saulais *et al.* (2019) considered
14 ‘Dish of the Day’ nudges to increase vegetable selection but more study within the topic is
15 needed. The objective of this research therefore was to further investigate influencing factors
16 on vegetable consumption independently from fruit and discuss how these findings could
17 support sustainable food system development when eating out.

32 **2. Background**

33
34 It is well established that daily consumption of vegetables is beneficial to human health. Diets
35 high in vegetables have historically held a place in many governments dietary guidelines and
36 are widely recommended for their health promoting properties, due to concentrations of
37 essential nutrients, vitamins, minerals, and dietary fibre (Slavin and Lloyd, 2012). 400g of
38 vegetables per day has been demonstrated to increase life expectancy by 0.4 years (Fadnes *et al.*,
39 2022) but dietary intakes across the globe do not realise this amount and it is now one of
40 the top 10 risk factors contributing to global mortality, with 1.8 million deaths per year
41 attributable to diets low in vegetables (Global Burden of Disease Study, 2020). Poor dietary
42 behaviours are of significant global concern predominantly for young adults, as habits gained
43 at this time can be taken through to later life.

1
2
3 Notwithstanding, intensifying awareness of climate change and environmental sustainability
4 coupled with health concerns of poor dietary profile is shifting societal norms and many
5
6 people are now actively reducing their consumption of animal-based products and replacing
7
8 with plant-based options (Sajeev *et al.*, 2020). This highlights opportunities for credible
9
10 evidence-based policy interventions within hospitality to further support and promote
11
12 vegetable intake. A systematic review (Appleton *et al.*, 2018) to identify interventions to
13
14 increase intake of vegetables as a distinct food group isolated 77 studies, detailing 140
15
16 interventions, of which 133 (81 %) were conducted in children. They comprised of
17
18 interventions aimed to use or change hedonic factors, such as taste, liking and familiarity (n =
19
20 72), use or change environmental factors (n = 39), use or change cognitive factors (n = 19), or
21
22 a combination of strategies (n = 10). Increased vegetable acceptance, selection and/or
23
24 consumption were reported to some degree in 116 (83 %) interventions, but the majority of
25
26 effects seem small and inconsistent. From the study it appears that success is currently found
27
28 from environmental, educational and multi-component interventions, but publication bias is
29
30 likely, and long-term effects and cost-effectiveness are rarely considered. It is clear that food
31
32 consumer behaviour is highly complex with many external and internal influences on
33
34 perception, attitude and action and where a focus on long-term benefits and sustained
35
36 behaviour change is required. Certain population groups such as young adults are also
37
38 noticeably absent from the current list of tried interventions (Appleton *et al.*, 2018).

39 40 41 42 43 44 45 46 47 *2.1. Factors influencing consumption in young adults*

48
49 The WHO (2018) advises that developing healthy eating habits in adolescence are the
50
51 foundation for good health in adulthood. Young adults (18-30 years of age) are an 'at-risk'
52
53 group for poor dietary behaviours and less healthy food choices (Howse *et al.*, 2018). Young
54
55 adults can find themselves at a transitory stage in their lives, with an increasing level of
56
57 independence and identity development, where eating habits are less influenced by parental
58
59
60

1
2
3 food behaviour, and unhealthy dietary habits can prevail. Parental vegetable intake has been
4 shown to be positively associated with adolescents' vegetable consumption (Pearson *et al.*,
5 2009), yet as this age group move away from the home environment, they are more affected
6 by convenience, peer sociocultural norms, obtaining peer social approval and peer influence
7 (Orben *et al.*, 2020). Studies have found that flatmates had great influence by giving social
8 support and acting as role models towards vegetable consumption (Hartman *et al.*, 2013).
9 Parental food behaviour and friends' social pressure have been considered to have both
10 positive (parents) and negative (friends) influences on individual eating habits in college
11 students (Sogari *et al.*, 2018). Given that it is well documented that young adults as a group
12 have a tendency to make unhealthy food choices which are convenient and that do not meet
13 current dietary recommendations (Poobalan *et al.*, 2014) this is a prime time for intervention
14 to influence positive consumption. Another factor associated with low vegetable consumption
15 is that some have unappealing sensory properties, such as bitter tastes (Dinehart *et al.*, 2006).
16 However, not all are identified in this way and some vegetable dishes could benefit with the
17 addition of a flavoured dip to improve acceptance (Savage *et al.*, 2013). Repeated exposure
18 has been advocated to increase vegetable liking and consumption, as has the use of rewards
19 but effect sizes are small (Appleton *et al.*, 2018; Bernardo *et al.*, 2021). Rodrigues *et al.*
20 (2019), summarises worldwide data regarding vegetable consumption from almost 70
21 thousand college students. The findings demonstrate that the majority of young adults do not
22 consume vegetables as recommended, or in sufficient quantities to satisfy relevant guidelines.
23 No consumption patterns according to country or region were apparent, although being
24 female was the more frequent predictor associated with a higher intake. Other factors such as
25 normal weight, living in the family home, importance given to healthy eating, higher
26 socioeconomic level, more openness to new experiences i.e., reduced neophobia, greater
27 nutrition knowledge, being more active and drinking less alcohol were all associated with a

2
3 higher intake. Availability and familiarity appear to be a key proximal determinant of
4 consumption, especially when the figure for fruit is also added (Rodrigues *et al.*, 2019).

5 6 7 8 *2.2 Health Belief Model*

9
10 The Health Belief Model (HBM) is one of the most widely used conceptual frameworks in
11 health behaviour research to explain change and maintenance of health-related behaviours
12 (Champion and Skinner, 2008). The model latterly suggests that four constructs can predict
13 health behaviour: perceived risk susceptibility, perceived risk severity, benefits to action and
14 barriers to action. It is intended to be utilised as a guiding framework for health behaviour
15 intentions by assuming that people want to avoid negative health outcomes and that they will
16 adopt behaviours which they believe will protect them from illness.
17

18 Perceived risk is assessed according to an individual's perception of his or her susceptibility
19 to the threat. For example, if a young adult has a friend or family member that is suffering
20 from a diet related disease this may heighten their perceived risk of susceptibility (Luquis and
21 Kensinger, 2018). Perceived benefits refer to people's belief about whether a health
22 behaviour they choose to undertake will enable them to manage a health risk. For example, if
23 a person believes consuming more vegetables, will help them lead healthier lives (Smith *et*
24 *al.*, 2019), maintain a healthy weight and fit their perception of ethically approved choice
25 (Urbanovich and Bevan, 2020), then they are more likely to consider adopting this change.
26 Barriers to action could be poor cooking skills, convenience, mood, and sensory appeal
27 whereas cues to action could be familiarity provided by an enabling environment. Despite
28 there being some studies investigating the application of the HBM on fruit and vegetable
29 consumption (Diddana *et al.*, 2018; Wright *et al.*, 2018), there *is* limited data related to young
30 adults and the influencing factors on vegetable consumption independently from fruits.
31 The present study provides valuable insights into how health beliefs may impact eating
32 behaviours for young adults, a population at the crucial stage of transitioning into

1
2
3 independent nutritional practices. Based on the HBM it is hypothesised that an individual's
4 likelihood of eating vegetables is determined by his or her health beliefs that consumption of
5 vegetables will improve overall Health (H2) by emphasising Natural content, (H1) and
6 Weight control (H3), acknowledging benefit i.e., Ethical concerns (H4), whilst overcoming
7 barriers to action, such as Convenience (H5), Familiarity (H6), Sensory appeal (H7), Mood
8 (H8) and Cooking skills (H9) (Figure 1). Additionally, it is proposed that where an individual
9 may not always be able to modify a given set of behaviours simply by wishing to do so, their
10 Self-efficacy (H10) may be considered a key intervening factor (Tsai *et al.*, 2021). Self-
11 efficacy refers to an individual's own conviction in his or her ability to make a health-related
12 adjustment in his or her life.

21
22
23
24
25
26 Variables for hypothesis and sociodemographic characteristics for study were selected based
27 on the literature and where, for example, vegetables being high in water and fibre content but
28 low in calories and energy density are beneficial for health and weight control. Research has
29 shown that consumers' perceptions of naturalness are important for the acceptance of foods
30 (Román *et al.*, 2017) as is ethical persuasion based on concerns for the environment. Cooking
31 skills or lack of have been identified as a reason for not preparing vegetables and hence
32 consuming them which can be related to convenience when considering young adults
33 (Rodrigues *et al.*, 2019). Other research has indicated that a high total intake of fruits and
34 vegetables, and some of their specific subgroups including green leafy vegetables, may
35 promote higher levels of optimism and self-efficacy although also could be a barrier if mood
36 is low (Gardner *et al.*, 2014). A positive mood increases the salience of long-term goals such
37 as health, leading to preference for foods such as vegetables whereas a negative mood leads
38 to greater preference for indulgent foods that tend to be processed and high in both fat and
39 sugar (Gardner *et al.*, 2014). Familiarity and sensory appeal were identified in the VeggieEAT
40 project (<https://microsites.bournemouth.ac.uk/veggieat/>) as important factors related to

consumption (Appleton *et al.*, 2019; Hartwell *et al.*, 2020). Therefore, consistent with the literature, the proposed Health Belief model specification included background factors of naturalness, attitude towards health, weight control, ethical concern, convenience, familiarity, sensory appeal, mood, cooking skills and self-efficacy. These were mapped onto the four constructs of predicting health behaviour namely perceived risk susceptibility, perceived risk severity, benefits to action and barriers to action to elucidate the research aim of investigating key factors that encourage vegetable intake by young adults.

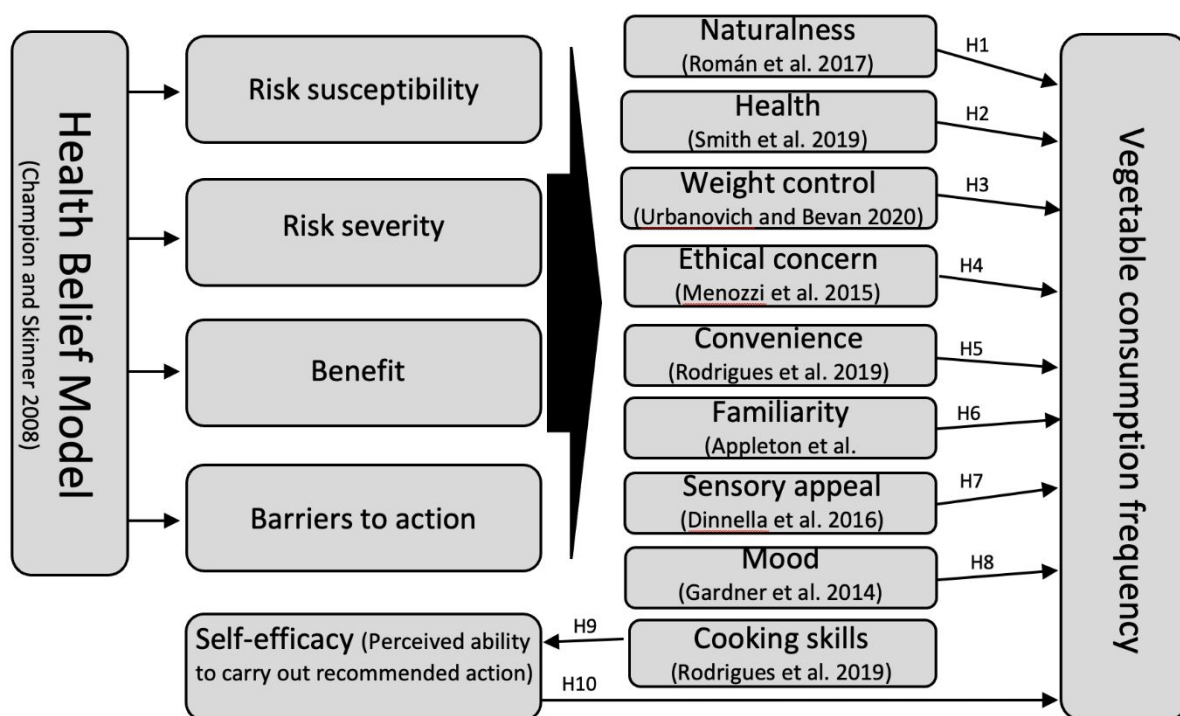

Figure 1: The Health Belief Model as a conceptual framework.

Menozzi *et al.* (2015) taking the Theory of Planned Behaviour to explain vegetable consumption in young adults suggested that, since the most detailed substantial information about the determinants of a given behaviour is contained in a person's behavioural, normative and control beliefs; factors of a personal nature such as mood, attitude to ethical issues and perception of naturalness are expected to influence intentions and behaviour. They propose

1
2
3 that providing factual information on the material consequences of eating vegetables
4 regularly, in particular short-term health implications, may improve consumers' attitude.
5
6 They also recommended that perceived social pressure could be improved by providing more
7
8 information about other same age peers behaviour related to vegetable consumption and
9
10 providing a setting in which social comparison can occur (Menozzi *et al.*, 2015). The Health
11
12 Belief Model as a framework is ideal for expanding this research. If individuals regard
13
14 themselves as susceptible to a condition, believe that condition would have potentially
15
16 serious consequences, believe that a course of action available to them would be beneficial in
17
18 reducing either their susceptibility to or severity of the condition, and believe the anticipated
19
20 benefits of taking action outweigh the barriers to (or costs of) action, they are likely to take
21
22 action that they believe will reduce their risks (Champion and Skinner, 2008).
23
24
25
26
27

28 Dietary change gives substantial health gains for people of all ages and is predicted to be
29
30 larger the earlier changes are initiated in life. Hence for policy to be effective actions
31
32 affecting consumption need to focus on influencing variables whilst at a young age and to
33
34 gain an understanding of the significant predictive relationships between attitudes and
35
36 behaviours.
37
38

39 40 **3.0 Methodology**

41 42 *3.1 Experimental Design*

43
44 This research explores the potential for vegetable consumption by developing a causal
45
46 structural model with 'CONVEGF' (Frequency of Vegetable Consumption) as its outcome
47
48 and consumer characteristics as predictors. A quantitative methodology was selected as most
49
50 appropriate to answer the research question and hypotheses. This study expanded and
51
52 developed results from previous research, i.e., the VeggiEAT project together with a
53
54 previously validated questionnaire (which included 5 scales from a cross-culturally adapted
55
56 instrument used with university students in Brazil (Jomori *et al.*, 2017) and a cross-cultural
57
58
59
60

1
2
3 food choice questionnaire (Heitor *et al.*, 2015). The survey was pilot tested with an initial
4 group of students face to face to confirm that all questions were easy to understand. Internal
5 consistency and reliability were ensured by achieving a Cronbach's α of 0.892. By
6 convention a value above 0.80 is considered a strong reliability test for a scale used in human
7 research (Vaske, 2008). The risk of common method bias was controlled for by giving clear
8 instructions; ensuring anonymity of responses; avoiding complex and ambiguous items and
9 through the concise survey design (Kock *et al.*, 2021).

10 The survey was distributed online to students aged 18 -30 years enrolled in undergraduate
11 programs at universities in Florianópolis, Brazil. Questions, in order of presentation,
12 consisted of food related lifestyle, e.g., i) availability and accessibility of vegetables; ii)
13 cooking behaviour at home; iii) cooking behaviour away from home; iv) personal attitude
14 towards vegetables; v) self-efficacy for using vegetables and seasonings; vi) self-efficacy on
15 consumption of fresh vegetables; (from Jomori *et al.*, 2017) and vii) motives underlying the
16 selection of food (Heitor *et al.*, 2015). Additionally, socio- demographic characteristics (i.e.,
17 age, gender, parental education level) and personal characteristics (i.e., undergraduate course,
18 with whom they live, lunch location, dinner location) were retrieved. Attitudinal questions
19 were presented on a 5 point likert scale where 1 was strongly disagree and 5 strongly agree. A
20 5 point scale was used to ensure both discriminant results and simplicity of use (Joshi *et al.*,
21 2015). Previous studies have shown gender differences and living arrangements moderate
22 vegetable intake with more women reporting eating vegetables daily than men and debate
23 regarding the effect of living away from home reducing vegetable consumption (Rodrigues *et*
24 *al.*, 2019).

25 All questions were translated from English into Portuguese and then back translated to ensure
26 accuracy and rigour following the procedure and guidelines recommended by Brislin (1993).

1
2
3 Participants were sampled through a snowball sampling technique using both the researchers'
4 initial student contacts and then their networks. This approach involved the researchers
5 initially meeting with a small number of individuals and then requesting that these
6 participants helped to identify their peers who might also complete the survey (Kumar, 2005).
7
8 Snowball sampling is used successfully to gather a representative sample.

9
10 Inclusion criteria comprised students over 18 years old and enrolled on a university
11 programme. Exclusion criteria in analysis comprised of students over 30 years old, the age
12 range of young adults taken as 18-30 years as defined by Howse *et al.* (2018). Power
13 calculation illustrated the minimum sample required was $n=418$ considering 10%
14 loss/incomplete, 5% of random error and the inclusion of socio-demographic control
15 variables. A usable sample size of $n=444$ was achieved.

16 *3.2 Empirical Application*

17 Data analysis comprised descriptive and inferential statistical procedures. Structural Equation
18 Modelling was used to identify and measure the factors predicting Vegetable Consumption
19 Frequency (Izsó *et al.*, 2019).

20 An unprejudiced conceptual review of the association among measured variables was
21 undertaken to provide a theoretical starting point for the exploratory model of the factors
22 leading to increased frequency of vegetable consumption among young adults. The semantic-
23 theoretical approach to clustering of the measured variables allowed for the development of
24 conceptual terms for each cluster, thereby nominating them reflective indicators of the
25 composite variable conceptually named. Structural variables were required which plausibly
26 confirm that the measured indicators are indicative for the purpose of seeding the structural
27 model which will quantify the regressive links between predictor and predicted; and will
28 serve as an exploratory working hypothesis in operational form. The procedures for
29 validating, testing and optimising the model closely adhered to the guidance of Hair *et al.*

(2017). The quality of the model's terms ensure that only the strengths of the subjective process survive, and the weaker speculations were deleted or respecified. Analysis of the survey was by principal component analysis run in SmartPLS 3 software using the PLS-SEM algorithm as outlined in Hair *et al.* (2017). SmartPLS is a casual modelling approach which optimises the explained variance of the dependant variable and can model both formative and reflective variables (Hair, 2017). Its use was particularly well suited since many antecedent factors were formative, the sample size requirements were met and the complexity of the model could be accommodated (Kumar, 2018). The analysis was conducted to reduce the dimensionality of the large data set and for all tests. Throughout, "significance" implies $p \leq 0.05$.

3.2.1 Assessing and Optimising the Structural (Outer) Model

The aim of this stage was to produce a structural model which ensures that the Latent Variables (LV) generate reliable information for the inner model. The process entailed assessing whether properties of the outer model met criteria of acceptability. According to Hair *et al.* (2017) these properties along with their numerical criteria are as follows: In the case of reflective LV's convergent validity demonstrated magnitude of outer loadings on the parent LV, significant and greater than 0.7, and the average variance extracted (AVE) greater than 0.5. For internal consistency Cronbach's α should be greater than 0.7 and Composite Reliability (CR): between 0.7 and 0.9. To ensure Discriminant Validity of the LVs, indicators of a given LV should load substantially higher than on that LV than on any other LV, the Fornell-Larcker Criterion: square root of AVE should be greater than a given LV's correlation with any other LV and the Heterotrait-monotrait ratio (HTMT): bootstrapped confidence interval for all pairs of constructs should not include 1. To test for collinearity, outer VIFs should be less than 5.

3.2.2 Assessing and Optimising the Inner (Structural) Model

1
2
3 Subject to theoretical oversight, non-significant indicators and regression paths were deleted
4 or reconfigured and if appropriate, specifications of LVs and their indicator sets were
5
6 adjusted. For this inner model, regression coefficients, endogenous (dependant) LV variance
7
8 and the effect size of the exogenous LV's should be significant. Probabilities of estimates are
9
10 derived from 5000 bootstrapped samples. In order to assess the relation direction between the
11
12 predictor variables and the latent variables confirmatory, Tetrad analysis was conducted
13
14 following the guidance of Hair et al. (2017). In the final analysis, predictor LVs except HEA
15
16 are specified as formative. The final model (shown in Figure II) also explores the possibility
17
18 that CONVEG is better specified as two outcome LVs. This is to distinguish between self-
19
20 efficacy-promoted consumption, SEFF, and the more general frequency of consumption,
21
22 CONVEGF; and further to test the dependency SEFF → CONVEGF. Confirmatory Tetrad
23
24 Analysis also suggests that SEFF is reflective. To test for collinearity, inner VIFs should be
25
26 lower than 5. For assessment of the model fit we examined SRMR which was less than 0.08
27
28 demonstrating an acceptable model fit according to Hu & Bentler (1999).

37

38 **4.0 Results**

39
40 A usable sample of 444 was achieved. Of these, 76% were female and mean age was $22.1 \pm$
41
42 3.1 years, 41% were undergraduate students from health-related programmes and most of
43
44 them (98%) did not have children. Regarding students' cooking habits, 70% reported having
45
46 between 1 to 3 hours a day to cook at home and 84% considered that they knew how to cook.
47
48 With regards to the place where meals are usually eaten, 62% said they had lunch away from
49
50 home. Most respondents consumed vegetables daily (45%) or several times a week (39%),
51
52 and the main meals in which they included vegetables was lunch (95%). The vegetables
53
54 consumed more frequently among the sample were carrots (72%), lettuce (59%), tomatoes
55
56
57
58
59
60

(47%) and beetroot (34%). Otherwise, the vegetables they least liked were chayote (35%), rocket (20%), watercress (13%), eggplant (13%) and radish (12%).

Structural modelling was conducted to standardize the range of the continuous initial variables and produce the factors as related to the data regarding vegetable consumption. The initial structural model contained 10 factors measured by survey items, namely, Naturalness (NATUR), Health (HEA), Weight control (WEI), Ethical concern (ETHIC), Convenience (CON), Familiarity (FAM), Sensory appeal (SENS), Mood (MOO), Cooking skills (COO) and Self-efficacy (SEFF).

4.1 Structural Model

Non-significant model parameters (formative relationship acknowledged) included Weight control, Ethical concern, Convenience and Mood and therefore were discarded. As such, the final model contained six latent variables shown to have a significant causal effect on the outcome variable of Vegetable Consumption Frequency. Sampling adequacy was good (KMO=0.87) and fit acceptable (19% of residuals in reproduced correlation matrix >0.05).

Self-efficacy (SEFF) has an effect size of 0.503 which demonstrates that just over 50% of the total effect is explained by the relationships outlined, while Consumption of Vegetable Frequency (CONVEGF) has an effect size of 0.231.

Both Self Efficacy (SEFF) and Health (HEA) are found to be reflective constructs. Outer Loadings, and their probabilities are shown in Table 1. One Outer Loading does not meet the criterion ($heal3 = 0.559$) but is retained because it has an important role in explaining the purpose of the construct.

Strictly, four indicators $cbh1$, $sens1,2$ & $sefv6$ should have been omitted as they did not meet the criteria. They have been retained as despite the modest loading $cbh1 \rightarrow COO$ (0.454) and non-significant but passable loading $sefv6 \rightarrow COO$ (0.625) $sens1 \rightarrow SENS$ (0.657) and $sens2 \rightarrow SENS$ (0.682) they make a substantive contribution to their Latent Variable, sensory

1
2
3 appeal i.e., greater than 0.1 (Hair, 2017). Discriminant Validity of the Latent Variables
4
5 confirmed by Fornell-Larcker Criterion is shown in Table II.

Figure II. Structural model of vegetable consumption in young adults

Iterative evaluation and revision were undertaken until the structural model met the criteria of acceptability with structural paths being significant (see Table III).

{Insert Table III: Vegetable consumption in young adults outcome Latent Variables and motives underlying food selection here}

Findings in relation to hypothesis testing is summarised in Table IV.

{Insert Table IV: Hypothesis summary here}

1
2
3 Of the 10 Latent Variables identified in the hypotheses; 6, namely Health, Naturalness,
4
5 Sensory, Familiarity, Cooking skills and Self-efficacy (ability to prepare and consume
6
7 vegetables) provided significant causal effect on Frequency of Vegetable Consumption.
8
9
10 The higher the participant weighting for vegetable “Healthiness” and “Naturalness” and
11
12 “Self-Efficacy”, the higher consumption was likely to be. Whereas “Sensory” and
13
14 “Familiarity” factors had a negative influence. This may be supported by a notion of extreme
15
16 taste, unpleasantness of texture and smell which can be associated with some vegetables, as
17
18 was also found in the VeggiEAT project. The previous within-product research highlighted
19
20 that independently from familiarity and stated liking, main drivers of actual liking and
21
22 disliking are the same across countries and ages; sweetness, in opposition to bitterness and
23
24 sourness (Cliceri *et al.*, 2017; Appleton *et al.*, 2019). The concept of Familiarity is important
25
26 in that consumers like what they know and eat what they like (Aldridge *et al.*, 2009)
27
28 however, memory heuristics to food that has previously been eaten or experienced does not
29
30 discriminate between positive or negative experiences. Our findings demonstrate a negative
31
32 loading for Familiarity suggesting that in this sample of young adults, previous exposure to
33
34 some vegetables may have resulted in negative cues to action.
35
36
37
38
39
40 The model identifies that the Frequency of Vegetable Consumption is strongly influenced by
41
42 Self-efficacy promoted consumption (CONVEGS) which comprises participants knowledge
43
44 and experience of cooking with vegetables including the use of condiments to enhance taste
45
46 and palatability. In short, cooking skills are found to have a strongly positive impact on the
47
48 Frequency of Vegetable Consumption.
49
50
51
52
53

5.0 Discussion

54
55
56 It is accepted that there is insufficient vegetable consumption globally from young to old and
57
58 that there is a disease burden associated with this low intake. While studies have considered
59
60

1
2
3 perceptions of freshness, psychosocial, environmental and life course factors influencing fruit
4 consumption, there is very little comparable data on vegetables, and this constitutes an under
5 researched area (Bray and Hartwell, 2017). Notwithstanding, Brazil, a country which is the
6 world's largest beef exporter, has seen a dramatic shift toward plant-based diets. The number
7 of self-declared vegetarians in Brazil has nearly doubled over a six-year period, 30 million
8 people, or 14 percent of Brazilians, reported being vegetarian or vegan in 2018 (Brazilian
9 Institute of Public Opinion and Statistics, 2018). Nevertheless, there is potential to reach out
10 to more of the population especially young adults.

11
12 Previous interventions have focused mostly on expanding consumer knowledge on the
13 benefits of increasing their intake of vegetables, based on the assumption that better
14 information would lead to healthier choices. As identified, numerous factors can interfere
15 with this knowledge and a better understanding of these aspects is needed in order to improve
16 the efficiency of public health policies. Initiatives such as Veg City
17 (<https://www.vegcities.org/>), Peas Please (<https://foodfoundation.org.uk/>) and Veg Power
18 (<https://vegpower.org.uk/>) are campaigns to drive up general vegetable consumption,
19 however, as yet young adults as a target population are not considered.

20
21 Using the Health Belief Model has enabled us to achieve a better understanding of vegetable
22 consumption and factors which relate to attitude and behaviour. Taking these factors and
23 debating within the four constructs that predict within the HBM, that is, perceived risk
24 susceptibility, perceived risk severity, benefits to action and barriers to action have allowed a
25 more comprehensive understanding of vegetable consumption within young adults. A
26 structured model approach allowed us to test certain hypotheses where the goodness of fit
27 met criteria required and demonstrated minimal discrepancy between observed values and the
28 values expected under the model in question.

1
2
3 The findings provide support that young adults value naturalness (0.167 $p=0.004$) and
4 perceived benefits to health (0.128 $p=0.013$). Direction of relationship suggests that
5 nutritional composition, such as increased fibre, and general health are important to young
6 adults. Concerns about health and perceived benefit of healthy eating have been found in
7 previous research as significantly affecting vegetable intake and intentions (Menozzi *et al.*,
8 2015). Likewise, associations between familiarity and liking or preference have been noted
9 (Appleton *et al.*, 2019); however, in this study Familiarity was shown to be negatively related
10 (-0.123 $p=0.002$), a direction not expected. Sensory as a latent variable was significant
11 however also as a negative value (-0.114 $p=0.010$) and therefore supports that sensory appeal
12 or lack of is important when considering vegetable consumption amongst young adults.
13 Ethical concern (-0.006 $p=0.9$) was discarded as were other factors such as convenience (-
14 0.059 $p=0.2$), weight control (-0.048 $p=0.3$), and mood (-0.067 $p=0.56$). Self-efficacy (SEFF)
15 summarises the perceived ease or difficulty of performing a behaviour and was found to
16 strongly influence action in a positive way (0.311 $p<0.000$), particularly through cooking
17 skills (0.709 $p=0.00$).

18
19 The HBM provides an appropriate framework for consideration of key factors that can
20 encourage young adults to increase vegetable consumption whilst also reflecting consumer
21 attitude trajectory. Glasson *et al.* (2011) directly compared the determinants of fruit and
22 vegetable consumption and indicated that there are significant differences in consumption
23 levels, barriers, knowledge, and stages of readiness (HBM) when fruit and vegetables are
24 considered as separate groups. It is highlighted that health promotion planners and policy
25 makers should consider interventions that focus on improving vegetable consumption in
26 preference to fruit (Glasson *et al.*, 2011). This could be in the form of providing factual
27 information on the material consequences of eating vegetables regularly, in particularly for
28 health and the reduction in risk of susceptibility/severity of disease. Findings from the
29

55
56
57
58
59
60

1
2
3 VeggieEAT project demonstrated a role for liking and a particular concern for health benefits
4 (Appleton *et al.*, 2017). Vegetables are considered essential for well-balanced diets since they
5
6 supply vitamins, minerals, dietary fibre, and phytochemicals (Dias, 2012), notwithstanding
7
8 compared to fruits they are poorly consumed probably due to many having a bitter sensory
9
10 profile. In past research (Cliceri *et al.*, 2017; Appleton *et al.*, 2019), highly liked vegetables
11
12 (carrots, tomatoes, green salad) have been identified, characterized by innately liked tastes
13
14 (sweet, umami), delicate flavour and bright appealing colour. Other highly disliked
15
16 vegetables consisted of cauliflower and broccoli, characterized by disliked sensations such as
17
18 bitter taste and less preferred flavour. The emerging policy for the importance of promoting
19
20 vegetable products has coincided with a surging consumer interested in healthy eating and
21
22 other lifestyle changes, which has been highlighted during the COVID pandemic (Mintel,
23
24 2021). Evidence from the Nielsen Global Health and Wellness Survey (2015), conducted in
25
26 60 countries and involving 30,000 consumers, supports that the most desirable food attributes
27
28 are freshness, naturalness, and minimal processing with consumers perceiving a close
29
30 connection between “natural” and “healthy”. It is important to consumers that food products
31
32 are natural as grown and produced in a traditional way and in accordance with nature (Román
33
34 *et al.*, 2017), a profile clearly associated with vegetables. It is also clear that sensory
35
36 attributes play a part in consumption decision. Nevertheless, this need not be a barrier for
37
38 vegetable dishes, innovative recipe design can ‘disguise’ objections and availability promote
39
40 neophilia (Saulais *et al.*, 2019). The presentation of a larger variety of vegetables in
41
42 hospitality has been shown to positively affect consumption while little variety has been
43
44 reported as an obstacle (Ensaif *et al.*, 2015). Self-efficacy encompassing frequency of home
45
46 cooking influences the likelihood of young adult vegetable consumption which can be
47
48 reinforced by healthful marketing. This research has identified and therefore accepted the
49
50 hypotheses that positive predictor variables for vegetable consumption are Health (H2),
51
52
53
54
55
56
57
58
59
60

1
2
3 Naturalness (H1), Cooking skills (H9) and Self-efficacy (H10) whereas Sensory appeal (H7)
4 and Familiarity (H6) are negative dimensions and barriers to overcome.
5
6

7 8 *5.1 Study Limitations*

9
10 While this study attracted a large sample of young adults, it should be acknowledged that the
11 sample was geographically placed in Brazil notwithstanding the likely generalisability of the
12 results cannot be ignored. The social demographics of our sample identify that these young
13 adults were all of college education. Although care was taken to design the survey tool so as
14 to minimise the risk of common method bias, it's influence cannot be totally excluded.
15
16

17 Further research could add confidence that these study findings are applicable to different
18 consumer groups. Several challenges are evident when considering the HBM as a theory to
19 predict health related behaviour (Champion and Skinner, 2008). It couples severity with
20 perceived susceptibility, which is a strength, compared with models that conceptualize threat
21 as a perceived risk alone. However, the relationship between risk and severity in forming a
22 threat is not always clear. In addition, its simplicity alone could be considered a limitation,
23 the HBM is a reductionistic, rational exchange framework which argues that individuals
24 systematically list and weigh the barriers and benefits of a behaviour. This might not always
25 be the case and emotion can be a major influence (Hartwell et al., 2013) hence the inclusion
26 of mood (although discarded as non-significant) within our instrument as a predictor variable.

47 **6.0 Conclusion and implications**

48
49 Future vulnerability of ecosystems to climate change will be strongly influenced by the past,
50 present and future development of human society, including consideration of the overall
51 sustainability of consumption and production (Intergovernmental Panel on Climate Change,
52 IPCC, 2022). Increasing healthful choices available to consumers (United Nations, 2021)
53 while eating out will impact. Food outside the home accounts for half total food expenditure
54
55
56
57
58
59
60

1
2
3 (Roberto et al., 2010) and hospitality unlike the food industry has been slow to respond to the
4
5 emerging agenda of health and sustainability. The competitive nature of the market means
6
7 that there is a resistance to change and cooperation between companies as an avoidance of
8
9 risk.

10
11
12 Historically, research programmes within the field have had a unidimensional aspect such as
13
14 nutrition but this does not take into account the broader issues such as biodiversity,
15
16 sustainability (with the accompanying muddy legal definition) and consumer science. It
17
18 means that the academic influence so far to hospitality has been somewhat inadequate, biased
19
20 towards food waste and missing the rising potential of consideration of the circular economy
21
22 from a broader aspect. This has been recognised for example by Sodhexo who has developed
23
24 the Plant+ initiative to be used in universities and publication of our existing research in
25
26 Playbook for Guiding Diners towards Plant-Rich dishes (WRI.org, 2019). Based on the
27
28 ecological model for sustainability it has been demonstrated that operational aspects could be
29
30 successful for example, availability, menu planning and healthful marketing to encourage the
31
32 consumption of vegetables (Bandoni *et al.*, 2011). From a social ecological perspective,
33
34 increasing access to affordable fresh fruits and vegetables in communities has shown to
35
36 encourage both intake and health improvement (Abildso *et al.*, 2019). However, achieving
37
38 impact requires a step change in food system development minimising reliance on
39
40 unsustainable use of planetary resources and the promotion of more plant based/vegetable
41
42 meals. Young adults are at the forefront to build healthier, more sustainable communities
43
44 which support transformation and achieve the UN Sustainable Development Goals (2015) by
45
46 2030. There is a 'bottom up' swell of consumer demand matched by a 'top down' policy
47
48 drive, towards more healthful consumption. It is clear that now is the time to navigate and act
49
50 on a compelling evidence base for this societal change. Hospitality environments such as
51
52 college and university canteens lend themselves to enabling peer to peer settings where good
53
54
55
56
57
58
59
60

1
2
3 practice can be exploited. Providing a role model of tasty vegetable dish alternatives could be
4
5 the answer and a move towards encouraging a hospitality sector that is sustainable, resilient,
6
7 competitive, diverse, responsible and performant in its provision of accessible, healthy, and
8
9 sustainable meals.
